

1/27/00
JCT13 U.S. PTO

01-31-00

IN THE UNITED STATES PATENT AND TRADEMARK OFFICE
REQUEST FOR FILING NEW UTILITY PATENT APPLICATION UNDER 37 CFR 1.53(b)
(Case No. P043D2C3C)

jc525 U.S. PTO
09/492982

01/27/00

To the Assistant Commission for Patents
Washington, D.C. 20231

Sir:

Transmitted herewith for filing under 35 U.S.C. 111(a) and 37 C.F.R. §1.53(b) is a new utility patent application for:

Title: INTEGRATED CIRCUIT I/O USING A
HIGH PERFORMANCE BUS INTERFACE

Inventors: Michael Farmwald
Mark Horowitz

This application is a **CONTINUATION APPLICATION** of:

Inventors: Michael Farmwald
Mark Horowitz

Ser. No.: 09/252,997

Art Unit: 2818

Filed: February 19, 1999

Examiner: T. Nguyen

Title: METHOD OF OPERATING A MEMORY
HAVING A VARIABLE DATA OUTPUT
LENGTH AND A PROGRAMMABLE REGISTER

To effect the above-requested filing today:

1. Attached is a copy of the prior application as originally filed, including:
 - [X] Specification, Claims, and Abstract (125 pages)
 - [X] Drawings: 1 set of **formal** drawings having 14 sheets
 - [X] Original Declaration and Power of Attorney (2 pages)
2. Incorporation by Reference: The entire disclosure of the prior application, from which a copy of the oath or declaration is supplied, is considered as being part of the disclosure of the

also revokes all other powers of attorney. Accordingly, kindly address all future communications to:

Neil A. Steinberg, Esq.
Rambus Inc.
2465 Latham Street
Mountain View, California 94040

Telephone No. 650-944-7772
Facsimile No. 650-428-0914

4. The Examiner's attention is directed to both the second paragraph of guideline (2) in MPEP 609 and to the last paragraph of MPEP 2001.06(b) and to the submission in the prior application of the Information Disclosure Statements and document copies filed in Application Serial Nos. 09/196,199 and 09/252,997.
5. Attached is a **PRELIMINARY AMENDMENT** which, among other things, cancels claims 1-150, and adds new claims 151-175. This Preliminary Amendment is to be entered **BEFORE** fee calculation.

6. **FILING FEE**
(BASED ON THE NUMBER OF CLAIMS AS FILED AND CHANGED BY PRELIMINARY AMENDMENT)

Basic Fee \$ 690.00

Additional Fees:

Surcharge for more than 20 total claims (5 * \$18) \$ 90.00
Surcharge for more than 3 independent claims (0 * 78) . . . \$ - 0 -
Surcharge for multiple dependent claims \$ - 0 -

Total Filing Fee \$ 780.00

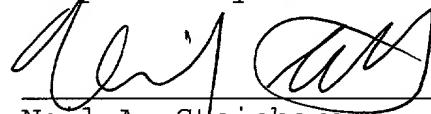

7. Manner of Payment:

A check payable to the Commissioner of Patents and Trademarks, in the amount of \$ _____ is enclosed as payment of the Total Filing Fee.

Please charge my Deposit Account No. 50-0998 in the amount of \$780.00 to cover the above fees. A duplicate copy of this sheet is enclosed.

[XX] The Commissioner is hereby authorized to charge any fees which may be required, or credit any overpayment to Deposit Account No. 50-0998. A duplicate copy of this sheet is enclosed.

Respectfully submitted,

Neil A. Steinberg

PRELIMINARY AMENDMENT

Dear Sir:

Prior to the examination of the above-referenced application,
kindly amend the application as follows:

IN THE ABSTRACT:

Please delete the Abstract of the Disclosure and substitute
the attached Abstract of the Disclosure.

IN THE TITLE:

Please delete the title and substitute --METHOD OF OPERATING
A MEMORY DEVICE HAVING A VARIABLE DATA INPUT LENGTH--.

IN THE SPECIFICATION:

On page 1, line 8, insert --This application is a continuation
of Application No. 09/252,997 (still pending), which is a

continuation of Application No. 09/196,199, filed on November 20, 1998 (still pending), which is a continuation of Application No. 08/798,520, filed on February 10, 1997 (now U.S. Patent 5,841,580); which is a division of Application No. 08/448,657, filed May 24, 1995 (now U.S. Patent 5,638,334); which is a division of Application No. 08/222,646, filed on March 31, 1994 (now U.S. Patent 5,513,327); which is a continuation of Application No. 07/954,945, filed on September 30, 1992 (now U.S. Patent 5,319,755); which is a continuation of Application No. 07/510,898, filed on April 18, 1990 (now abandoned).--

On page 3, line 9, delete "micro-processor" and substitute --microprocessor--.

On page 6, line 1, delete "4,646,279" and substitute --4,646,270--.

On page 10, line 18, delete "Figure 7 shows" and substitute --Figures 7a and 7b show--.

On page 10, line 21, delete "Figure 8 shows" and substitute --Figures 8a and 8b show--.

On page 34, line 4, after "devices" insert --do--.

On page 41, line 1, delete "or' " and substitute -- or--.

On page 45, line 17, delete "Fig. 7" and substitute --Figures 7a and 7b--.

On page 47, line 2, delete "Figure 8" and substitute --Figure 8a--.

On page 47, line 5, delete "from left to right" and substitute -- from right to left--.

On page 47, line 8, delete "right" and substitute --left--.

On page 47, line 9, delete the first "left" and substitute --right--.

On page 49, line 22, delete "primay" and substitute --primary--.

On page 54, line 13, delete "70" and substitute --69--.

On page 56, line 2, delete "Figurell" and substitute --Figure 11--.

On page 60, line 10, after "147" insert --A, B--.

IN THE CLAIMS:

Kindly cancel claims 1-150, without prejudice.

Kindly add the following claims:

-- 151. A method of controlling a memory device, wherein the memory device includes a plurality of memory cells, the method of controlling the memory device comprises:

4 providing first block size information to the memory device,
5 wherein the first block size information defines a first amount of
6 data to be input by the memory device in response to a write
7 request; and

8 issuing a first write request to the memory device, wherein in
9 response to the first write request the memory device inputs the
10 first amount of data corresponding to the first block size
11 information.

1 152. The method of claim 151 wherein the memory device inputs
2 the first amount of data synchronously with respect to an external
3 clock signal.

1 153. The method of claim 151 further including:
2 providing second block size information to the memory device,
3 wherein the second block size information defines a second amount
4 of data to be input by the memory device in response to a write
5 request; and
6 issuing the second write request to the memory device, wherein
7 in response to the second write request, the memory device inputs
8 the amount of data corresponding to the second block size
9 information.

1 154. The method of claim 151 wherein the first block size
2 information and the first write request are included in a request
3 packet.

1 155. The method of claim 154 wherein the first block size
2 information and the first write request are included in the same
3 request packet.

1 156. The method of claim 151 further including providing
2 the amount of data corresponding to the first block size
3 information to the memory device.

1 157. The method of claim 156 wherein the data is provided to
2 the memory device after a delay time transpires.

1 158. The method of claim 156 wherein the delay time is
2 representative of a number of clock cycles of a clock signal.

1 159. The method of claim 151 wherein the first block size
2 information is a binary representation of the amount of data to be
3 input in response to the first write request.

1 160. The method of claim 151 wherein the first amount of data
2 corresponding to the first block size information is input
3 synchronously during a plurality of clock cycles of the external
4 clock signal.

1 161. A method of operation of a memory device, wherein the
2 memory device includes a plurality of memory cells, the method of
3 operation of the memory device comprises:

4 receiving first block size information from a bus controller,
5 wherein the first block size information defines a first amount of
6 data to be input by the memory device in response to a write
7 request;

8 receiving a first write request from the bus controller; and
9 inputting the first amount of data corresponding to the first
10 block size information in response to the first write request.

1 162. The method of claim 161 wherein the data corresponding to
2 the first block size information is sampled synchronously with
3 respect to the external clock signal.

1 163. The method of claim 161 further including:
2 receiving second block size information, wherein the second
3 block size information defines a second amount of data to be input
4 in response to a second write request;
5 receiving a second write request from the bus controller; and
6 inputting the amount of data corresponding to the second block
7 size information, in response to the second write request.

1 164. The method of claim 161 wherein the first block size
2 information and the first write request are included in a request
3 packet.

1 165. The method of claim 164 wherein the first block size
2 information and the first write request are included in the same
3 request packet.

1 166. The method of claim 161 wherein the first block size
2 information is a binary representation of the first amount of data
3 to be input in response to the first write request.

1 167. The method of claim 161 wherein the first amount of data
2 corresponding to the first block size information is input

3 synchronously during a plurality of clock cycles of an external
4 clock signal.

1 168. The method of claim 161 further including generating an
2 internal clock signal using a delay locked loop and an external
3 clock signal wherein the first amount of data corresponding to the
4 first block size information is input synchronously with respect to
5 the internal clock signal.

1 169. The method of claim 161 further including generating
2 first and second internal clock signals using clock generation
3 circuitry and an external clock signal wherein the first amount of
4 data corresponding to the first block size information is input
5 synchronously with respect to the first and second internal clock
6 signals.

1 170. The method of claim 169 wherein the first and second
2 internal clock signals are generated by a delay lock loop.

1 171. A method of operation of an integrated circuit, wherein
2 the integrated circuit includes a memory array having a plurality
3 of memory cells, the method of operation comprises:

4 receiving block size information, wherein the block size
5 information defines a first amount of data to be input from a bus
6 in response to a write request;
7 receiving a first write request; and

8 inputting the first amount of data corresponding to the block
9 size information in response to the first write request.

1 172. The method of claim 171 further including storing the
2 first amount of data corresponding to the block size information in
3 the memory array.

1 173. The method of claim 171 wherein the block size
2 information and the first write request are included in a request
3 packet.

1 174. The method of claim 171 wherein the first block size
2 information is a binary representation of the first amount of data
3 to be input in response to the first write request.

1 175. The method of claim 171 wherein the first block size
2 information is provided by a controller.--

REMARKS

This Preliminary Amendment seeks to place this application in condition for allowance. This application is a continuation of Application No. 09/252,997, which is a continuation of Application No. 09/196,199. Application Serial Nos. 09/252,997 and 09/196,199 are pending.

Applicants request priority to Application Serial No. 07/510,898, filed April 18, 1990, now abandoned. Applicants request such priority through Application No. 09/252,997 (still pending), which is a continuation of Application No. 09/196,199, filed on November 20, 1998 (still pending), which is a continuation of Application No. 08/798,520, filed on February 10, 1997 (now U.S. Patent 5,841,580); which is a division of Application No. 08/448,657, filed May 24, 1995 (now U.S. Patent 5,638,334); which is a division of Application No. 08/222,646, filed on March 31, 1994 (now U.S. Patent 5,513,327); which is a continuation of Application No. 07/954,945, filed on September 30, 1992 (now U.S. Patent 5,319,755); which is a continuation of Application No. 07/510,898, filed on April 18, 1990 (now abandoned).

Accordingly, Applicants claim the benefit of the filing date of Application Serial No. 07/510,898 -- i.e., April 18, 1990. The specification has been amended to identify the continuation or related U.S. application data identified above. No new matter has been added.

In this continuation application, Applicants present new claims which set forth novel and unobvious features of Applicants' invention. Applicants submit new claims 151-175 to more fully protect the instant invention. No new matter has been added.

The newly submitted claims are believed to be fully supported by the specification -- see, for example, Figures 2 and 10-13; page 14, line 3 to page 15, line 2; page 15, lines 18 to page 16, line 7; page 20, line 20 to page 21, line 20; page 23, line 6 to page 24, line 2; page 27, line 23 to page 28, line 20; page 46, line 19

to page 48, line 17; page 53, line 23 to page 59, line 2; page 71, line 23 to page 72, line 21, page 73, lines 20 to page 74, line 31; and page 115, lines 10-22.

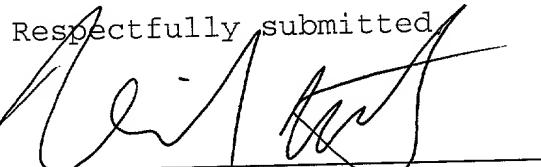

Applicants have also amended the specification to correct obvious spelling, typographical and grammatical errors. No new matter has been added.

In addition, a new Abstract of the Disclosure is attached hereto. No new matter has been added.

Finally, accompanying this Preliminary Amendment is a Request to Approve Drawing Changes. In that Request, Applicants seek to amend Figure 10 to more fully reflect the discussion in the specification, in particular, page 55, lines 12-16 and page 58, lines 13-23. The proposed changes are indicated in red. No new matter has been added. Applicants respectfully request that the Examiner approve the proposed changes to Figure 10. A new Figure 10 which incorporates the changes is also attached to the Request.

CONCLUSION

Applicants request entry of the foregoing amendment prior to examination of this application. Applicants submit that all of the claims present patentable subject matter. Accordingly, Applicants respectfully request allowance of all of the claims.

Respectfully submitted

Neil A. Steinberg

Date: January 27, 2000

ABSTRACT OF THE DISCLOSURE

A method of controlling a memory device, wherein the memory device includes a plurality of memory cells. The method includes providing first block size information to the memory device, wherein the first block size information defines a first amount of data to be input by the memory device in response to a write request. The method further includes issuing a write request to the memory device, wherein in response to the write request the memory device inputs the first amount of data corresponding to the first block size information.

5

Integrated Circuit I/O Using A
High Performance Bus Interface

FIELD OF THE INVENTION

10

An integrated circuit bus interface for computer and video systems is described which allows high speed transfer of blocks of data, particularly to and from memory devices, with reduced power consumption and increased system reliability. A new method of physically implementing the bus architecture is also described.

15

BACKGROUND OF THE INVENTION

20

Semiconductor computer memories have traditionally been designed and structured to use one memory device for each bit, or small group of bits, of any individual computer word, where the word size is governed by the choice of computer. Typical word sizes range from 4 to 64 bits. Each memory device typically is connected in parallel to a series of address lines and connected to one of a series of data lines. When the computer seeks to 25 read from or write to a specific memory location, an address is put on the address lines and some or all of the memory devices are activated using a separate device select line for each needed device. One or more devices may be connected to each data line but typically only a small number of data lines are connected to

25

a single memory device. Thus data line 0 is connected to device(s) 0, data line 1 is connected to device(s) 1, and so on. Data is thus accessed or provided in parallel for each memory read or write operation. For the system to operate properly, 5 every single memory bit in every memory device must operate dependably and correctly.

To understand the concept of the present invention, it is helpful to review the architecture of conventional memory devices. Internal to nearly all types of memory devices (including the most widely used Dynamic Random Access Memory (DRAM), Static RAM (SRAM) and Read Only Memory (ROM) devices), a large number of bits are accessed in parallel each time the system carries out a memory access cycle. However, only a small percentage of accessed bits which are available internally each time the memory device is cycled ever make it across the device boundary to the external world.

Referring to Fig. 1, all modern DRAM, SRAM and ROM designs have internal architectures with row (word) lines 5 and column (bit) lines 6 to allow the memory cells to tile a two dimensional area 1. One bit of data is stored at the intersection of each word and bit line. When a particular word line is enabled, all of the corresponding data bits are transferred onto the bit lines. Some prior art DRAMs take advantage of this organization to reduce the number of pins needed to transmit the address. The address of a given memory

cell is split into two addresses, row and column, each of which can be multiplexed over a bus only half as wide as the memory cell address of the prior art would have required.

5 COMPARISON WITH PRIOR ART

10

Prior art memory systems have attempted to solve the problem of high speed access to memory with limited success. U.S. Patent No. 3,821,715 (Hoff et. al.), was issued to Intel Corporation for the earliest 4-bit micro-processor. That patent describes a bus connecting a single central processing unit (CPU) with multiple RAMs and ROMs. That bus multiplexes addresses and data over a 4-bit wide bus and uses point-to-point control signals to select particular RAMs or ROMs. The access time is fixed and only a single processing element is permitted. There is no block-mode type of operation, and most important, not all of the interface signals between the devices are bused (the ROM and RAM control lines and the RAM select lines are point-to-point).

20

In U.S. Patent No. 4,315,308 (Jackson), a bus connecting a single CPU to a bus interface unit is described. The invention uses multiplexed address, data, and control information over a single 16-bit wide bus. Block-mode operations are defined, with the length of the block sent as part of the control sequence. In addition, variable access-time operations using a "stretch" cycle signal are provided. There are no

25

multiple processing elements and no capability for multiple outstanding requests, and again, not all of the interface signals are bused.

5 In U.S. Patent No. 4,449,207 (Kung, et. al.), a DRAM is described which multiplexes address and data on an internal bus. The external interface to this DRAM is conventional, with separate control, address and data connections.

10 In U.S. Patent Nos. 4,764,846 and 4,706,166 (Go), a 3-D package arrangement of stacked die with connections along a single edge is described. Such packages are difficult to use because of the point-to-point wiring required to interconnect conventional memory devices with processing elements. Both 15 patents describe complex schemes for solving these problems. No attempt is made to solve the problem by changing the interface.

15 In U.S. Patent No. 3,969,706 (Proebsting, et. al.), the current state-of-the-art DRAM interface is described. The address is two-way multiplexed, and there are separate pins for data and control (RAS, CAS, WE, CS). The number of pins grows 20 with the size of the DRAM, and many of the connections must be made point-to-point in a memory system using such DRAMs.

25 There are many backplane buses described in the prior art, but not in the combination described or having the features of this invention. Many backplane buses multiplex addresses and data on a single bus (e.g., the NU bus). ELXSI and others have implemented split-transaction buses (U.S. Patent No. 4,595,923

and 4,481,625 (Roberts)). ELXSI has also implemented a relatively low-voltage-swing current-mode ECL driver (approximately 1 V swing). Address-space registers are implemented on most backplane buses, as is some form of block mode operation.

5

10

15

20

25

Nearly all modern backplane buses implement some type of arbitration scheme, but the arbitration scheme used in this invention differs from each of these. U.S. Patent Nos. 4,837,682 (Culler), 4,818,985 (Ikeda), 4,779,089. (Theus) and 4,745,548 (Blahut) describe prior art schemes. All involve either log N extra signals, (Theus, Blahut), where N is the number of potential bus requestors, or additional delay to get control of the bus (Ikeda, Culler). None of the buses described in patents or other literature use only bused connections. All contain some point-to-point connections on the backplane. None of the other aspects of this invention such as power reduction by fetching each data block from a single device or compact and low-cost 3-D packaging even apply to backplane buses.

The clocking scheme used in this invention has not been used before and in fact would be difficult to implement in backplane buses due to the signal degradation caused by connector stubs. U.S. Patent No. 4,247,817 (Heller) describes a clocking scheme using two clock lines, but relies on ramp-shaped clock signals in contrast to the normal rise-time signals used in the present invention.

In U.S. Patent No. 4,646,279 (Voss), a video RAM is described which implements a parallel-load, serial-out shift register on the output of a DRAM. This generally allows greatly improved bandwidth (and has been extended to 2, 4 and greater width shift-out paths.) The rest of the interfaces to the DRAM (RAS, CAS, multiplexed address, etc.) remain the same as for conventional DRAMs.

One object of the present invention is to use a new bus interface built into semiconductor devices to support high-speed access to large blocks of data from a single memory device by an external user of the data, such as a microprocessor, in an efficient and cost-effective manner.

Another object of this invention is to provide a clocking scheme to permit high speed clock signals to be sent along the bus with minimal clock skew between devices.

Another object of this invention is to allow mapping out defective memory devices or portions of memory devices.

Another object of this invention is to provide a method for distinguishing otherwise identical devices by assigning a unique identifier to each device.

Yet another object of this invention is to provide a method for transferring address, data and control information over a relatively narrow bus and to provide a method of bus arbitration when multiple devices seek to use the bus simultaneously.

Another object of this invention is to provide a method of distributing a high-speed memory cache within the DRAM chips of a memory system which is much more effective than previous cache methods.

5 Another object of this invention is to provide devices, especially DRAMs, suitable for use with the bus architecture of the invention.

SUMMARY OF INVENTION

10 The present invention includes a memory subsystem comprising at least two semiconductor devices, including at least one memory device, connected in parallel to a bus, where the bus includes a plurality of bus lines for carrying substantially all address, data and control information needed by said memory devices, where the control information includes device-select information and the bus has substantially fewer bus lines than the number of bits in a single address, and the bus carries device-select information without the need for separate device-select lines connected directly to individual devices.

15 Referring to Fig. 2, a standard DRAM 13, 14, ROM (or SRAM) 12, microprocessor CPU 11, I/O device, disk controller or other special purpose device such as a high speed switch is modified to use a wholly bus-based interface rather than the prior art combination of point-to-point and bus-based wiring used with conventional versions of these devices. The new bus

includes clock signals, power and multiplexed address, data and control signals. In a preferred implementation, 8 bus data lines and an AddressValid bus line carry address, data and control information for memory addresses up to 40 bits wide. Persons skilled in the art will recognize that 16 bus data lines or other numbers of bus data lines can be used to implement the teaching of this invention. The new bus is used to connect elements such as memory, peripheral, switch and processing units.

In the system of this invention, DRAMs and other devices receive address and control information over the bus and transmit or receive requested data over the same bus. Each memory device contains only a single bus interface with no other signal pins. Other devices that may be included in the system can connect to the bus and other non-bus lines, such as input/output lines. The bus supports large data block transfers and split transactions to allow a user to achieve high bus utilization. This ability to rapidly read or write a large block of data to one single device at a time is an important advantage of this invention.

The DRAMs that connect to this bus differ from conventional DRAMs in a number of ways. Registers are provided which may store control information, device identification, device-type and other information appropriate for the chip such as the address range for each independent portion of the device.

New bus interface circuits must be added and the internals of

prior art DRAM devices need to be modified so they can provide and accept data to and from the bus at the peak data rate of the bus. This requires changes to the column access circuitry in the DRAM, with only a minimal increase in die size. A circuit is 5 provided to generate a low skew internal device clock for devices on the bus, and other circuits provide for demultiplexing input and multiplexing output signals.

High bus bandwidth is achieved by running the bus at a very high clock rate (hundreds of MHz). This high clock rate is 10 made possible by the constrained environment of the bus. The bus lines are controlled-impedance, doubly-terminated lines. For a data rate of 500 MHz, the maximum bus propagation time is less 15 than 1 ns (the physical bus length is about 10 cm). In addition, because of the packaging used, the pitch of the pins can be very close to the pitch of the pads. The loading on the bus resulting from the individual devices is very small. In a preferred implementation, this generally allows stub capacitances of 1-2 pF and inductances of 0.5 - 2 nH. Each device 15, 16, 17, shown in Figure 3, only has pins on one side and these pins connect 20 directly to the bus 18. A transceiver device 19 can be included to interface multiple units to a higher order bus through pins 20.

A primary result of the architecture of this invention is to increase the bandwidth of DRAM access. The invention also

reduces manufacturing and production costs, power consumption, and increases packing density and system reliability.

BRIEF DESCRIPTION OF THE DRAWINGS

5 Figure 1 is a diagram which illustrates the basic 2-D organization of memory devices.

Figure 2 is a schematic block diagram which illustrates the parallel connection of all bus lines and the serial Reset line to each device in the system.

10 Figure 3 is a perspective view of a system of the invention which illustrates the 3-D packaging of semiconductor devices on the primary bus.

Figure 4 shows the format of a request packet.

15 Figure 5 shows the format of a retry response from a slave.

Figure 6 shows the bus cycles after a request packet collision occurs on the bus and how arbitration is handled.

20 Figure 7 shows the timing whereby signals from two devices can overlap temporarily and drive the bus at the same time.

Figure 8 shows the connection and timing between bus clocks and devices on the bus.

Figure 9 is a perspective view showing how transceivers can be used to connect a number of bus units to a transceiver

bus. Figure 10 is a block and schematic diagram of input/output circuitry used to connect devices to the bus.

Figure 11 is a schematic diagram of a clocked sense-amplifier used as a bus input receiver.

15 DETAILED DESCRIPTION

The present invention is designed to provide a high speed, multiplexed bus for communication between processing devices and memory devices and to provide devices adapted for use in the bus system. The invention can also be used to connect processing devices and other devices, such as I/O interfaces or disk controllers, with or without memory devices on the bus. The bus consists of a relatively small number of lines connected in parallel to each device on the bus. The bus carries substantially all address, data and control information needed by devices for communication with other devices on the bus. In many

systems using the present invention, the bus carries almost every signal between every device in the entire system. There is no need for separate device-select lines since device-select information for each device on the bus is carried over the bus.

5 There is no need for separate address and data lines because address and data information can be sent over the same lines. Using the organization described herein, very large addresses (40 bits in the preferred implementation) and large data blocks (1024 bytes) can be sent over a small number of bus lines (8 plus one control line in the preferred implementation).

10 Virtually all of the signals needed by a computer system can be sent over the bus. Persons skilled in the art recognize that certain devices, such as CPUs, may be connected to other signal lines and possibly to independent buses, for example a bus to an independent cache memory, in addition to the bus of this invention. Certain devices, for example cross-point switches, could be connected to multiple, independent buses of this invention. In the preferred implementation, memory devices are provided that have no connections other than the bus connections described herein and CPUs are provided that use the bus of this invention as the principal, if not exclusive, connection to memory and to other devices on the bus.

20 All modern DRAM, SRAM and ROM designs have internal architectures with row (word) and column (bit) lines to efficiently tile a 2-D area. Referring to Fig. 1, one bit of

data is stored at the intersection of each word line 5 and bit line 6. When a particular word line is enabled, all of the corresponding data bits are transferred onto the bit lines. This data, about 4000 bits at a time in a 4 Mbit DRAM, is then loaded 5 into column sense amplifiers 3 and held for use by the I/O circuits.

In the invention presented here, the data from the sense amplifiers is enabled 32 bits at a time onto an internal device bus running at approximately 125 MHz. This internal 10 device bus moves the data to the periphery of the devices where the data is multiplexed into an 8-bit wide external bus interface, running at approximately 500 MHz.

The bus architecture of this invention connects master or bus controller devices, such as CPUs, Direct Memory Access devices (DMAs) or Floating Point Units (FPUs), and slave devices, such as DRAM, SRAM or ROM memory devices. A slave device responds to control signals; a master sends control signals. Persons skilled in the art realize that some devices may behave as both master and slave at various times, depending on the mode 15 of operation and the state of the system. For example, a memory device will typically have only slave functions, while a DMA controller, disk controller or CPU may include both slave and master functions. Many other semiconductor devices, including 20 I/O devices, disk controllers, or other special purpose devices

such as high speed switches can be modified for use with the bus of this invention.

Each semiconductor device contains a set of internal registers, preferably including a device identification (device 5 ID) register, a device-type descriptor register, control registers and other registers containing other information relevant to that type of device. In a preferred implementation, semiconductor devices connected to the bus contain registers which specify the memory addresses contained within that device 10 and access-time registers which store a set of one or more delay times at which the device can or should be available to send or receive data.

Most of these registers can be modified and preferably are set as part of an initialization sequence that occurs when 15 the system is powered up or reset. During the initialization sequence each device on the bus is assigned a unique device ID number, which is stored in the device ID register. A bus master can then use these device ID numbers to access and set appropriate registers in other devices, including access-time 20 registers, control registers, and memory registers, to configure the system. Each slave may have one or several access-time registers (four in a preferred embodiment). In a preferred embodiment, one access-time register in each slave is permanently or semi-permanently programmed with a fixed value to facilitate

certain control functions. A preferred implementation of an initialization sequence is described below in more detail.

All information sent between master devices and slave devices is sent over the external bus, which, for example, may be 5 8 bits wide. This is accomplished by defining a protocol whereby a master device, such as a microprocessor, seizes exclusive control of the external bus (i.e., becomes the bus master) and initiates a bus transaction by sending a request packet (a sequence of bytes comprising address and control information) to one or more slave devices on the bus. An address can consist of 10 16 to 40 or more bits according to the teachings of this invention. Each slave on the bus must decode the request packet to see if that slave needs to respond to the packet. The slave that the packet is directed to must then begin any internal processes needed to carry out the requested bus transaction at 15 the requested time. The requesting master may also need to transact certain internal processes before the bus transaction begins. After a specified access time the slave(s) respond by returning one or more bytes (8 bits) of data or by storing 20 information made available from the bus. More than one access time can be provided to allow different types of responses to occur at different times.

A request packet and the corresponding bus access are 25 separated by a selected number of bus cycles, allowing the bus to be used in the intervening bus cycles by the same or other

masters for additional requests or brief bus accesses. Thus multiple, independent accesses are permitted, allowing maximum utilization of the bus for transfer of short blocks of data.

Transfers of long blocks of data use the bus efficiently even without overlap because the overhead due to bus address, control and access times is small compared to the total time to request and transfer the block.

Device Address Mapping

Another unique aspect of this invention is that each memory device is a complete, independent memory subsystem with all the functionality of a prior art memory board in a conventional backplane-bus computer system. Individual memory devices may contain a single memory section or may be subdivided into more than one discrete memory section. Memory devices preferably include memory address registers for each discrete memory section. A failed memory device (or even a subsection of a device) can be "mapped out" with only the loss of a small fraction of the memory, maintaining essentially full system capability. Mapping out bad devices can be accomplished in two ways, both compatible with this invention.

The preferred method uses address registers in each memory device (or independent discrete portion thereof) to store information which defines the range of bus addresses to which this memory device will respond. This is similar to prior art

schemes used in memory boards in conventional backplane bus systems. The address registers can include a single pointer, usually pointing to a block of known size, a pointer and a fixed or variable block size value or two pointers, one pointing to the 5 beginning and one to the end (or to the "top" and "bottom") of each memory block. By appropriate settings of the address registers, a series of functional memory devices or discrete memory sections can be made to respond to a contiguous range of addresses, giving the system access to a contiguous block of good 10 memory, limited primarily by the number of good devices connected to the bus. A block of memory in a first memory device or memory section can be assigned a certain range of addresses, then a block of memory in a next memory device or memory section can be assigned addresses starting with an address one higher (or lower, depending on the memory structure) than the last address of the 15 previous block.

Preferred devices for use in this invention include device-type register information specifying the type of chip, including how much memory is available in what configuration on 20 that device. A master can perform an appropriate memory test, such as reading and writing each memory cell in one or more selected orders, to test proper functioning of each accessible discrete portion of memory (based in part on information like device ID number and device-type) and write address values (up to 25 40 bits in the preferred embodiment, 10^{12} bytes), preferably

contiguous, into device address-space registers. Non-functional or impaired memory sections can be assigned a special address value which the system can interpret to avoid using that memory.

The second approach puts the burden of avoiding the bad devices on the system master or masters. CPUs and DMA controllers typically have some sort of translation look-aside buffers (TLBs) which map virtual to physical (bus) addresses. With relatively simple software, the TLBs can be programmed to use only working memory (data structures describing functional memories are easily generated). For masters which don't contain TLBs (for example, a video display generator), a small, simple RAM can be used to map a contiguous range of addresses onto the addresses of the functional memory devices.

Either scheme works and permits a system to have a significant percentage of non-functional devices and still continue to operate with the memory which remains. This means that systems built with this invention will have much improved reliability over existing systems, including the ability to build systems with almost no field failures.

20

Bus

The preferred bus architecture of this invention comprises 11 signals: BusData[0:7]; AddrValid; Clk1 and Clk2; plus an input reference level and power and ground lines connected in parallel to each device. Signals are driven onto

the bus during conventional bus cycles. The notation "Signal[i:j]" refers to a specific range of signals or lines, for example, BusData[0:7] means BusData0, BusData1, . . . , BusData7. The bus lines for BusData[0:7] signals form a byte-wide, 5 multiplexed data/address/control bus. AddrValid is used to indicate when the bus is holding a valid address request, and instructs a slave to decode the bus data as an address and, if the address is included on that slave, to handle the pending request. The two clocks together provide a synchronized, high speed clock for all the devices on the bus. In addition to the 10 bused signals, there is one other line (ResetIn, ResetOut) connecting each device in series for use during initialization to assign every device in the system a unique device ID number (described below in detail).

15 To facilitate the extremely high data rate of this external bus relative to the gate delays of the internal logic, the bus cycles are grouped into pairs of even/odd cycles. Note that all devices connected to a bus should preferably use the same even/odd labeling of bus cycles and preferably should begin 20 operations on even cycles. This is enforced by the clocking scheme.

Protocol and Bus Operation

25 The bus uses a relatively simple, synchronous, split-transaction, block-oriented protocol for bus transactions. One

of the goals of the system is to keep the intelligence concentrated in the masters, thus keeping the slaves as simple as possible (since there are typically many more slaves than masters). To reduce the complexity of the slaves, a slave should 5 preferably respond to a request in a specified time, sufficient to allow the slave to begin or possibly complete a device-internal phase including any internal actions that must precede the subsequent bus access phase. The time for this bus access phase is known to all devices on the bus - each master being 10 responsible for making sure that the bus will be free when the bus access begins. Thus the slaves never worry about arbitrating for the bus. This approach eliminates arbitration in single master systems, and also makes the slave-bus interface simpler.

In a preferred implementation of the invention, to 15 initiate a bus transfer over the bus, a master sends out a request packet, a contiguous series of bytes containing address and control information. It is preferable to use a request packet containing an even number of bytes and also preferable to start each packet on an even bus cycle.

20 The device-select function is handled using the bus data lines. AddrValid is driven, which instructs all slaves to decode the request packet address, determine whether they contain the requested address, and if they do, provide the data back to the master (in the case of a read request) or accept data from 25 the master (in the case of a write request) in a data block

transfer. A master can also select a specific device by transmitting a device ID number in a request packet. In a preferred implementation, a special device ID number is chosen to indicate that the packet should be interpreted by all devices on the bus. This allows a master to broadcast a message, for example to set a selected control register of all devices with the same value.

The data block transfer occurs later at a time specified in the request packet control information, preferably beginning on an even cycle. A device begins a data block transfer almost immediately with a device-internal phase as the device initiates certain functions, such as setting up memory addressing, before the bus access phase begins. The time after which a data block is driven onto the bus lines is selected from values stored in slave access-time registers. The timing of data for reads and writes is preferably the same; the only difference is which device drives the bus. For reads, the slave drives the bus and the master latches the values from the bus. For writes the master drives the bus and the selected slave latches the values from the bus.

In a preferred implementation of this invention shown in Figure 4, a request packet 22 contains 6 bytes of data -- 4.5 address bytes and 1.5 control bytes. Each request packet uses all nine bits of the multiplexed data/address lines (AddrValid 23 + BusData[0:7] 24) for all six bytes of the request packet.

Setting 23 AddrValid = 1 in an otherwise unused even cycle indicates the start of an request packet (control information). In a valid request packet, AddrValid 27 must be 0 in the last byte. Asserting this signal in the last byte invalidates the request packet. This is used for the collision detection and arbitration logic (described below). Bytes 25-26 contain the first 35 address bits, Address[0:35]. The last byte contains AddrValid 27 (the invalidation switch) and 28, the remaining address bits, Address[36:39], and BlockSize[0:3] (control information).

The first byte contains two 4 bit fields containing control information, AccessType[0:3], an op code (operation code) which, for example, specifies the type of access, and Master[0:3], a position reserved for the master sending the packet to include its master ID number. Only master numbers 1 through 15 are allowed - master number 0 is reserved for special system commands. Any packet with Master[0:3] = 0 is an invalid or special packet and is treated accordingly.

The AccessType field specifies whether the requested operation is a read or write and the type of access, for example, whether it is to the control registers or other parts of the device, such as memory. In a preferred implementation, AccessType[0] is a Read/Write switch: if it is a 1, then the operation calls for a read from the slave (the slave to read the requested memory block and drive the memory contents onto the

bus); if it is a 0, the operation calls for a write into the slave (the slave to read data from the bus and write it to memory). AccessType[1:3] provides up to 8 different access types for a slave. AccessType[1:2] preferably indicates the timing of the response, which is stored in an access-time register, AccessRegN. The choice of access-time register can be selected directly by having a certain op code select that register, or indirectly by having a slave respond to selected op codes with pre-selected access times (see table below). The remaining bit, AccessType[3] may be used to send additional information about the request to the slaves.

10
15
20

One special type of access is control register access, which involves addressing a selected register in a selected slave. In the preferred implementation of this invention, AccessType[1:3] equal to zero indicates a control register request and the address field of the packet indicates the desired control register. For example, the most significant two bytes can be the device ID number (specifying which slave is being addressed) and the least significant three bytes can specify a register address and may also represent or include data to be loaded into that control register. Control register accesses are used to initialize the access-time registers, so it is preferable to use a fixed response time which can be preprogrammed or even hard wired, for example the value in AccessReg0, preferably 8

cycles. Control register access can also be used to initialize or modify other registers, including address registers.

The method of this invention provides for access mode control specifically for the DRAMs. One such access mode 5 determines whether the access is page mode or normal RAS access. In normal mode (in conventional DRAMs and in this invention), the DRAM column sense amps or latches have been precharged to a value intermediate between logical 0 and 1. This precharging allows access to a row in the RAM to begin as soon as the access request for either inputs (writes) or outputs (reads) is received and allows the column sense amps to sense data quickly. In page mode 10 (both conventional and in this invention), the DRAM holds the data in the column sense amps or latches from the previous read or write operation. If a subsequent request to access data is directed to the same row, the DRAM does not need to wait for the data to be sensed (it has been sensed already) and access time for this data is much shorter than the normal access time. Page mode generally allows much faster access to data but to a smaller 15 block of data (equal to the number of sense amps). However, if the requested data is not in the selected row, the access time is longer than the normal access time, since the request must wait for the RAM to precharge before the normal mode access can start. Two access-time registers in each DRAM preferably contain the 20 access times to be used for normal and for page-mode accesses, respectively. 25

The access mode also determines whether the DRAM should precharge the sense amplifiers or should save the contents of the sense amps for a subsequent page mode access. Typical settings are "precharge after normal access" and "save after page mode access" but "precharge after page mode access" or "save after normal access" are allowed, selectable modes of operation. The DRAM can also be set to precharge the sense amps if they are not accessed for a selected period of time.

In page mode, the data stored in the DRAM sense amplifiers may be accessed within much less time than it takes to read out data in normal mode (~10-20 nS vs. 40-100 nS). This data may be kept available for long periods. However, if these sense amps (and hence bit lines) are not precharged after an access, a subsequent access to a different memory word (row) will suffer a precharge time penalty of about 40-100 nS because the sense amps must precharge before latching in a new value.

The contents of the sense amps thus may be held and used as a cache, allowing faster, repetitive access to small blocks of data. DRAM-based page-mode caches have been attempted in the prior art using conventional DRAM organizations but they are not very effective because several chips are required per computer word. Such a conventional page-mode cache contains many bits (for example, 32 chips x 4Kbits) but has very few independent storage entries. In other words, at any given point in time the sense amps hold only a few different blocks of memory

"locales" (a single block of 4K words, in the example above). Simulations have shown that upwards of 100 blocks are required to achieve high hit rates (>90% of requests find the requested data already in cache memory) regardless of the size of each block.

5 See, for example, Anant Agarwal, et. al., "An Analytic Cache Model," *ACM Transactions on Computer Systems*, Vol. 7(2), pp. 184-215 (May 1989).

10 The organization of memory in the present invention allows each DRAM to hold one or more (4 for 4MBit DRAMS) separately- addressed and independent blocks of data. A personal computer or workstation with 100 such DRAMs (i.e. 400 blocks or locales) can achieve extremely high, very repeatable hit rates (98-99% on average) as compared to the lower (50-80%), widely varying hit rates using DRAMS organized in the conventional fashion. Further, because of the time penalty associated with the deferred precharge on a "miss" of the page-mode cache, the conventional DRAM-based page-mode cache generally has been found 15 to work less well than no cache at all.

For DRAM slave access, the access types are preferably used in the following way:

<u>AccessType[1:3]</u>	<u>Use</u>	<u>AccessTime</u>
0	Control Register Access	Fixed, 8[AccessReg0]
1	Unused	Fixed, 8[AccessReg0]
2-3	Unused	AccessReg1
4-5	Page Mode DRAM access	AccessReg2
6-7	Normal DRAM access	AccessReg3

Persons skilled in the art will recognize that a series of available bits could be designated as switches for controlling these access modes. For example:

AccessType[2] = page mode/normal switch

AccessType[3] = precharge/save-data switch

BlockSize[0:3] specifies the size of the data block transfer. If BlockSize[0] is 0, the remaining bits are the binary representation of the block size (0-7). If BlockSize[0] is 1, then the remaining bits give the block size as a binary power of 2, from 8 to 1024. A zero-length block can be interpreted as a special command, for example, to refresh a DRAM without returning any data, or to change the DRAM from page mode to normal access mode or vice-versa.

<u>BlockSize[0:21]</u>	<u>Number of Bytes in Block</u>
0-7	0-7 respectively
8	8
9	16
10	32
11	64
12	128
13	256
14	512
15	1024

Persons skilled in the art will recognize that other block size encoding schemes or values can be used.

In most cases, a slave will respond at the selected access time by reading or writing data from or to the bus over bus lines BusData[0:7] and AddrValid will be at logical 0. In a preferred embodiment, substantially each memory access will involve only a single memory device, that is, a single block will be read from or written to a single memory device.

Retry Format

In some cases, a slave may not be able to respond correctly to a request, e.g., for a read or write. In such a situation, the slave should return an error message, sometimes called a N(o)ACK(nowledge) or retry message. The retry message can include information about the condition requiring a retry, but this increases system requirements for circuitry in both slave and masters. A simple message indicating only that an error has occurred allows for a less complex slave, and the

master can take whatever action is needed to understand and correct the cause of the error.

For example, under certain conditions a slave might not be able to supply the requested data. During a page-mode access, the DRAM selected must be in page mode and the requested address must match the address of the data held in the sense amps or latches. Each DRAM can check for this match during a page-mode access. If no match is found, the DRAM begins precharging and returns a retry message to the master during the first cycle of the data block (the rest of the returned block is ignored). The master then must wait for the precharge time (which is set to accommodate the type of slave in question, stored in a special register, PreChargeReg), and then resend the request as a normal DRAM access (AccessType = 6 or 7).

In the preferred form of the present invention, a slave signals a retry by driving AddrValid true at the time the slave was supposed to begin reading or writing data. A master which expected to write to that slave must monitor AddrValid during the write and take corrective action if it detects a retry message.

Figure 5 illustrates the format of a retry message 28 which is useful for read requests, consisting of 23 AddrValid=1 with Master[0:3] = 0 in the first (even) cycle. Note that AddrValid is normally 0 for data block transfers and that there is no master 0 (only 1 through 15 are allowed). All DRAMs and masters can easily recognize such a packet as an invalid request packet.

and therefore a retry message. In this type of bus transaction all of the fields except for Master[0:3] and AddrValid 23 may be used as information fields, although in the implementation described, the contents are undefined. Persons skilled in the art recognize that another method of signifying a retry message is to add a DataInvalid line and signal to the bus. This signal could be asserted in the case of a NACK.

5 Bus Arbitration

10 In the case of a single master, there are by definition no arbitration problems. The master sends request packets and keeps track of periods when the bus will be busy in response to that packet. The master can schedule multiple requests so that the corresponding data block transfers do not overlap.

15 The bus architecture of this invention is also useful in configurations with multiple masters. When two or more masters are on the same bus, each master must keep track of all the pending transactions, so each master knows when it can send a request packet and access the corresponding data block transfer.

20 Situations will arise, however, where two or more masters send a request packet at about the same time and the multiple requests must be detected, then sorted out by some sort of bus arbitration.

25 There are many ways for each master to keep track of when the bus is and will be busy. A simple method is for each

master to maintain a bus-busy data structure, for example by maintaining two pointers, one to indicate the earliest point in the future when the bus will be busy and the other to indicate the earliest point in the future when the bus will be free, that is, the end of the latest pending data block transfer. Using this information, each master can determine whether and when there is enough time to send a request packet (as described above under Protocol) before the bus becomes busy with another data block transfer and whether the corresponding data block transfer will interfere with pending bus transactions. Thus each master must read every request packet and update its bus-busy data structure to maintain information about when the bus is and will be free.

With two or more masters on the bus, masters will occasionally transmit independent request packets during the same bus cycle. Those multiple requests will collide as each such master drives the bus simultaneously with different information, resulting in scrambled request information and neither desired data block transfer. In a preferred form of the invention, each device on the bus seeking to write a logical 1 on a BusData or AddrValid line drives that line with a current sufficient to sustain a voltage greater than or equal to the high-logic value for the system. Devices do not drive lines that should have a logical 0; those lines are simply held at a voltage corresponding to a low-logic value. Each master tests the voltage on at least

some, preferably all, bus data and the AddrValid lines so the master can detect a logical '1' where the expected level is '0' on a line that it does not drive during a given bus cycle but another master does drive.

5 Another way to detect collisions is to select one or more bus lines for collision signalling. Each master sending a request drives that line or lines and monitors the selected lines for more than the normal drive current (or a logical value of "1"), indicating requests by more than one master. Persons
10 skilled in the art will recognize that this can be implemented with a protocol involving BusData and AddrValid lines or could be implemented using an additional bus line.

In the preferred form of this invention, each master
15 detects collisions by monitoring lines which it does not drive to see if another master is driving those lines. Referring to Fig. 4, the first byte of the request packet includes the number of each master attempting to use the bus (Master[0:3]). If two masters send packet requests starting at the same point in time, the master numbers will be logical "or"ed together by at least
20 those masters, and thus one or both of the masters, by monitoring the data on the bus and comparing what it sent, can detect a collision. For instance if requests by masters number 2 (0010) and 5 (0101) collide, the bus will be driven with the value Master[0:3]=7 (0010 + 0101 = 0111). Master number 5 will detect
25 that the signal Master[2] = 1 and master 2 will detect that

Master[1] and Master[3] = 1, telling both masters that a collision has occurred. Another example is masters 2 and 11, for which the bus will be driven with the value Master[0:3]=11 (0010 + 1011 = 1011), and although master 11 can't readily detect this collision, master 2 can. When any collision is detected, each master detecting a collision drives the value of AddrValid 27 in byte 5 of the request packet 22 to 1, which is detected by all masters, including master 11 in the second example above, and forces a bus arbitration cycle, described below.

Another collision condition may arise where master A sends a request packet in cycle 0 and master B tries to send a request packet starting in cycle 2 of the first request packet, thereby overlapping the first request packet. This will occur from time to time because the bus operates at high speeds, thus the logic in a second-initiating master may not be fast enough to detect a request initiated by a first master in cycle 0 and to react fast enough by delaying its own request. Master B eventually notices that it wasn't supposed to try to send a request packet (and consequently almost surely destroyed the address that master A was trying to send), and, as in the example above of a simultaneous collision, drives a 1 on AddrValid during byte 5 of the first request packet 27 forcing an arbitration. The logic in the preferred implementation is fast enough that a master should detect a request packet by another master by cycle

3 of the first request packet, so no master is likely to attempt to send a potentially colliding request packet later than cycle 2.

Slave devices not need to detect a collision directly, but they must wait to do anything irrecoverable until the last byte (byte 5) is read to ensure that the packet is valid. A request packet with Master[0:3] equal to 0 (a retry signal) is ignored and does not cause a collision. The subsequent bytes of such a packet are ignored.

To begin arbitration after a collision, the masters wait a preselected number of cycles after the aborted request packet (4 cycles in a preferred implementation), then use the next free cycle to arbitrate for the bus (the next available even cycle in the preferred implementation). Each colliding master signals to all other colliding masters that it seeks to send a request packet, a priority is assigned to each of the colliding masters, then each master is allowed to make its request in the order of that priority.

Figure 6 illustrates one preferred way of implementing this arbitration. Each colliding master signals its intent to send a request packet by driving a single BusData line during a single bus cycle corresponding to its assigned master number (1-15 in the present example). During two-byte arbitration cycle 29, byte 0 is allocated to requests 1-7 from masters 1-7, respectively, (bit 0 is not used) and byte 1 is allocated to

5 requests 8-15 from masters 8-15, respectively. At least one device and preferably each colliding master reads the values on the bus during the arbitration cycles to determine and store which masters desire to use the bus. Persons skilled in the art will recognize that a single byte can be allocated for arbitration requests if the system includes more bus lines than masters. More than 15 masters can be accommodated by using additional bus cycles.

10 A fixed priority scheme (preferably using the master numbers, selecting lowest numbers first) is then used to prioritize, then sequence the requests in a bus arbitration queue which is maintained by at least one device. These requests are queued by each master in the bus-busy data structure and no further requests are allowed until the bus arbitration queue is 15 cleared. Persons skilled in the art will recognize that other priority schemes can be used, including assigning priority according to the physical location of each master.

System Configuration/Reset

20 In the bus-based system of this invention, a mechanism is provided to give each device on the bus a unique device identifier (device ID) after power-up or under other conditions as desired or needed by the system. A master can then use this device ID to access a specific device, particularly to set or 25 modify registers of the specified device, including the control

and address registers. In the preferred embodiment, one master is assigned to carry out the entire system configuration process. The master provides a series of unique device ID numbers for each unique device connected to the bus system. In the preferred embodiment, each device connected to the bus contains a special device-type register which specifies the type of device, for instance CPU, 4 MBit memory, 64 MBit memory or disk controller. The configuration master should check each device, determine the device type and set appropriate control registers, including access-time registers. The configuration master should check each memory device and set all appropriate memory address registers.

One means to set up unique device ID numbers is to have each device to select a device ID in sequence and store the value in an internal device ID register. For example, a master can pass sequential device ID numbers through shift registers in each of a series of devices, or pass a token from device to device whereby the device with the token reads in device ID information from another line or lines. In a preferred embodiment, device ID numbers are assigned to devices according to their physical relationship, for instance, their order along the bus.

In a preferred embodiment of this invention, the device ID setting is accomplished using a pair of pins on each device, ResetIn and ResetOut. These pins handle normal logic signals and are used only during device ID configuration. On each rising

edge of the clock, each device copies ResetIn (an input) into a four-stage reset shift register. The output of the reset shift register is connected to ResetOut, which in turn connects to ResetIn for the next sequentially connected device.

5 Substantially all devices on the bus are thereby daisy-chained together. A first reset signal, for example, while ResetIn at a device is a logical 1, or when a selected bit of the reset shift register goes from zero to non-zero, causes the device to hard reset, for example by clearing all internal registers and 10 resetting all state machines. A second reset signal, for example, the falling edge of ResetIn combined with changeable values on the external bus, causes that device to latch the contents of the external bus into the internal device ID register (Device[0:7]).

15 To reset all devices on a bus, a master sets the ResetIn line of the first device to a "1" for long enough to ensure that all devices on the bus have been reset (4 cycles times the number of devices -- note that the maximum number of devices on the preferred bus configuration is 256 (8 bits), so 20 that 1024 cycles is always enough time to reset all devices.) Then ResetIn is dropped to "0" and the BusData lines are driven with the first followed by successive device ID numbers, changing after every 4 clock pulses. Successive devices set those device ID numbers into the corresponding device ID register as the 25 falling edge of ResetIn propagates through the shift registers of

the daisy-chained devices. Figure 14 shows ResetIn at a first device going low while a master drives a first device ID onto the bus data lines BusData[0:3]. The first device then latches in that first device ID. After four clock cycles, the master 5 changes BusData[0:3] to the next device ID number and ResetOut at the first device goes low, which pulls ResetIn for the next daisy-chained device low, allowing the next device to latch in the next device ID number from BusData[0:3]. In the preferred embodiment, one master is assigned device ID 0 and it is the 10 responsibility of that master to control the ResetIn line and to drive successive device ID numbers onto the bus at the appropriate times. In the preferred embodiment, each device waits two clock cycles after ResetIn goes low before latching in a device ID number from BusData[0:3].

15 Persons skilled in the art recognize that longer device ID numbers could be distributed to devices by having each device read in multiple bytes from the bus and latch the values into the device ID register. Persons skilled in the art also recognize that there are alternative ways of getting device ID numbers to 20 unique devices. For instance, a series of sequential numbers could be clocked along the ResetIn line and at a certain time each device could be instructed to latch the current reset shift register value into the device ID register.

25 The configuration master should choose and set an access time in each access-time register in each slave to a

period sufficiently long to allow the slave to perform an actual, desired memory access. For example, for a normal DRAM access, this time must be longer than the row address strobe (RAS) access time. If this condition is not met, the slave may not deliver 5 the correct data. The value stored in a slave access-time register is preferably one-half the number of bus cycles for which the slave device should wait before using the bus in response to a request. Thus an access time value of '1' would indicate that the slave should not access the bus until at least 10 two cycles after the last byte of the request packet has been received. The value of AccessReg0 is preferably fixed at 8 (cycles) to facilitate access to control registers.

The bus architecture of this invention can include more than one master device. The reset or initialization sequence 15 should also include a determination of whether there are multiple masters on the bus, and if so to assign unique master ID numbers to each. Persons skilled in the art will recognize that there are many ways of doing this. For instance, the master could poll each device to determine what type of device it is, for example, 20 by reading a special register then, for each master device, write the next available master ID number into a special register.

ECC

Error detection and correction ("ECC") methods well known in the art can be implemented in this system. ECC 25

information typically is calculated for a block of data at the time that block of data is first written into memory. The data block usually has an integral binary size, e.g. 256 bits, and the ECC information uses significantly fewer bits. A potential problem arises in that each binary data block in prior art schemes typically is stored with the ECC bits appended, resulting in a block size that is not an integral binary power.

5 In a preferred embodiment of this invention, ECC information is stored separately from the corresponding data, which can then be stored in blocks having integral binary size. 10 ECC information and corresponding data can be stored, for example, in separate DRAM devices. Data can be read without ECC using a single request packet, but to write or read error- 15 corrected data requires two request packets, one for the data and a second for the corresponding ECC information. ECC information may not always be stored permanently and in some situations the ECC information may be available without sending a request packet or without a bus data block transfer.

20 In a preferred embodiment, a standard data block size

can be selected for use with ECC, and the ECC method will determine the required number of bits of information in a corresponding ECC block. RAMs containing ECC information can be programmed to store an access time that is equal to: (1) the access time of the normal RAM (containing data) plus the time to 25 access a standard data block (for corrected data) minus the time

to send a request packet (6 bytes); or (2) the access time of a normal RAM minus the time to access a standard ECC block minus the time to send a request packet. To read a data block and the corresponding ECC block, the master simply issues a request for 5 the data immediately followed by a request for the ECC block.

The ECC RAM will wait for the selected access time then drive its data onto the bus right after (in case (1) above) the data RAM has finished driving out the data block. Persons skilled in the art will recognize that the access time described in case (2) 10 above can be used to drive ECC data before the data is driven onto the bus lines and will recognize that writing data can be done by analogy with the method described for a read. Persons skilled in the art will also recognize the adjustments that must be made in the bus-busy structure and the request packet 15 arbitration methods of this invention in order to accommodate these paired ECC requests.

Since this system is quite flexible, the system 20 designer can choose the size of the data blocks and the number of ECC bits using the memory devices of this invention. Note that the data stream on the bus can be interpreted in various ways. For instance the sequence can be 2^n data bytes followed by 2^k ECC 25 bytes (or vice versa), or the sequence can be 2^k iterations of 8 data bytes plus 1 ECC byte. Other information, such as information used by a directory-based cache coherence scheme, can also be managed this way. See, for example, Anant Agarwal, et

al., "Scalable Directory Schemes for Cache Consistency," 15th International Symposium on Computer Architecture, June 1988, pp. 280-289. Those skilled in the art will recognize alternative methods of implementing ECC schemes that are within the teachings
5 of this invention.

Low Power 3-D Packaging

Another major advantage of this invention is that it drastically reduces the memory system power consumption. Nearly
10 all the power consumed by a prior art DRAM is dissipated in performing row access. By using a single row access in a single RAM to supply all the bits for a block request (compared to a row-access in each of multiple RAMs in conventional memory systems) the power per bit can be made very small. Since the
15 power dissipated by memory devices using this invention is significantly reduced, the devices potentially can be placed much closer together than with conventional designs.

The bus architecture of this invention makes possible an innovative 3-D packaging technology. By using a narrow, multiplexed (time-shared) bus, the pin count for an arbitrarily
20 large memory device can be kept quite small - on the order of 20 pins. Moreover, this pin count can be kept constant from one generation of DRAM density to the next. The low power dissipation allows each package to be smaller, with narrower pin
25 pitches (spacing between the IC pins). With current surface

mount technology supporting pin pitches as low as 20 mils, all off-device connections can be implemented on a single edge of the memory device. Semiconductor die useful in this invention preferably have connections or pads along one edge of the die 5 which can then be wired or otherwise connected to the package pins with wires having similar lengths. This geometry also allows for very short leads, preferably with an effective lead length of less than 4 mm. Furthermore, this invention uses only bused interconnections, i.e., each pad on each device is 10 connected by the bus to the corresponding pad of each other device.

The use of a low pin count and an edge-connected bus permits a simple 3-D package, whereby the devices are stacked and the bus is connected along a single edge of the stack. The fact 15 that all of the signals are bused is important for the implementation of a simple 3-D structure. Without this, the complexity of the "backplane" would be too difficult to make cost effectively with current technology. The individual devices in a stack of the present invention can be packed quite tightly 20 because of the low power dissipated by the entire memory system, permitting the devices to be stacked bumper-to-bumper or top to bottom. Conventional plastic-injection molded small outline (SO) packages can be used with a pitch of about 2.5 mm (100 mils), but the ultimate limit would be the device die thickness, which is

about an order of magnitude smaller, 0.2-0.5 mm using current wafer technology.

Bus Electrical Description

5 By using devices with very low power dissipation and

close physical packing, the bus can be made quite short, which in turn allows for short propagation times and high data rates. The bus of a preferred embodiment of the present invention consists

10 of a set of resistor-terminated controlled impedance transmission lines which can operate up to a data rate of 500 MHz (2 ns

cycles). The characteristics of the transmission lines are

strongly affected by the loading caused by the DRAMs (or other slaves) mounted on the bus. These devices add lumped capacitance to the lines which both lowers the impedance of the lines and

15 decreases the transmission speed. In the loaded environment, the bus impedance is likely to be on the order of 25 ohms and the propagation velocity about $c/4$ (c = the speed of light) or 7.5 cm/ns.

20 To operate at a 2 ns data rate, the transit time on the bus should preferably be kept under 1 ns, to leave 1 ns for the setup and hold time of the input receivers (described below) plus

clock skew. Thus the bus lines must be kept quite short, under about 8 cm for maximum performance. Lower performance systems may have much longer lines, e.g. a 4 ns bus may have 24 cm lines (3 ns transit time, 1 ns setup and hold time).

In the preferred embodiment, the bus uses current source drivers. Each output must be able to sink 50 mA, which provides an output swing of about 500 mV or more. In the preferred embodiment of this invention, the bus is active low.

5 The unasserted state (the high value) is preferably considered a logical zero, and the asserted value (low state) is therefore a logical 1. Those skilled in the art understand that the method of this invention can also be implemented using the opposite logical relation to voltage. The value of the unasserted state is set by the voltage on the termination resistors, and should be high enough to allow the outputs to act as current sources, while being as low as possible to reduce power dissipation. These constraints may yield a termination voltage about 2V above ground in the preferred implementation. Current source drivers cause 10 the output voltage to be proportional to the sum of the sources driving the bus.

15

Referring to Fig.7, although there is no stable condition where two devices drive the bus at the same time, conditions can arise because of propagation delay on the wires where one device, A 41, can start driving its part of the bus 44 20 while the bus is still being driven by another device, B 42 (already asserting a logical 1 on the bus). In a system using current drivers, when B 42 is driving the bus (before time 46), the value at points 44 and 45 is logical 1. If B 42 switches off 25 at time 46 just when A 41 switches on, the additional drive by

device A 41 causes the voltage at the output 44 of A 41 to drop briefly below the normal value. The voltage returns to its normal value at time 47 when the effect of device B 42 turning off is felt. The voltage at point 45 goes to logical 0 when 5 device B 42 turns off, then drops at time 47 when the effect of device A 41 turning on is felt. Since the logical 1 driven by current from device A 41 is propagated irrespective of the previous value on the bus, the value on the bus is guaranteed to settle after one time of flight (t_f) delay, that is, the time it takes a signal to propagate from one end of the bus to the other. 10 If a voltage drive was used (as in ECL wired-ORing), a logical 1 on the bus (from device B 42 being previously driven) would prevent the transition put out by device A 41 being felt at the most remote part of the system, e.g., device 43, until the 15 turnoff waveform from device B 42 reached device A 41 plus one time of flight delay, giving a worst case settling time of twice the time of flight delay.

Clocking

20 Clocking a high speed bus accurately without introducing error due to propagation delays can be implemented by having each device monitor two bus clock signals and then derive internally a device clock, the true system clock. The bus clock information can be sent on one or two lines to provide a 25 mechanism for each bused device to generate an internal device

clock with zero skew relative to all the other device clocks. Referring to Figure 8, in the preferred implementation, a bus clock generator 50 at one end of the bus propagates an early bus clock signal in one direction along the bus, for example on line 5 53 from left to right, to the far end of the bus. The same clock signal then is passed through the direct connection shown to a second line 54, and returns as a late bus clock signal along the bus from the far end to the origin, propagating from right to left. A single bus clock line can be used if it is left 10 unterminated at the far end of the bus, allowing the early bus clock signal to reflect back along the same line as a late bus clock signal.

Figure 8b illustrates how each device 51, 52 receives each of the two bus clock signals at a different time (because of propagation delay along the wires), with constant midpoint in 15 time between the two bus clocks along the bus. At each device 51, 52, the rising edge 55 of Clock1 53 is followed by the rising edge 56 of Clock2 54. Similarly, the falling edge 57 of Clock1 53 is followed by the falling edge 58 of Clock2 54. This 20 waveform relationship is observed at all other devices along the bus. Devices which are closer to the clock generator have a greater separation between Clock1 and Clock2 relative to devices farther from the generator because of the longer time required for each clock pulse to traverse the bus and return along line 25 54, but the midpoint in time 59, 60 between corresponding rising

or falling edges is fixed because, for any given device, the length of each clock line between the far end of the bus and that device is equal. Each device must sample the two bus clocks and generate its own internal device clock at the midpoint of the two.

Clock distribution problems can be further reduced by using a bus clock and device clock rate equal to the bus cycle data rate divided by two, that is, the bus clock period is twice the bus cycle period. Thus a 500 MHz bus preferably uses a 250 MHz clock rate. This reduction in frequency provides two benefits. First it makes all signals on the bus have the same worst case data rates -- data on a 500 MHz bus can only change every 2 ns. Second, clocking at half the bus cycle data rate makes the labeling of the odd and even bus cycles trivial, for example, by defining even cycles to be those when the internal device clock is 0 and odd cycles when the internal device clock is 1.

Multiple Buses

The limitation on bus length described above restricts the total number of devices that can be placed on a single bus. Using 2.5 mm spacing between devices, a single 8 cm bus will hold about 32 devices. Persons skilled in the art will recognize certain applications of the present invention wherein the overall data rate on the bus is adequate but memory or processing

requirements necessitate a much larger number of devices (many more than 32). Larger systems can easily be built using the teachings of this invention by using one or more memory subsystems, designated primary bus units, each of which consists of two or more devices, typically 32 or close to the maximum allowed by bus design requirements, connected to a transceiver device.

Referring to Figure 9, each primary bus unit can be mounted on a single circuit board 66, sometimes called a memory stick. Each transceiver device 19 in turn connects to a transceiver bus 65, similar or identical in electrical and other respects to the primary bus 18 described at length above. In a preferred implementation, all masters are situated on the transceiver bus so there are no transceiver delays between masters and all memory devices are on primary bus units so that all memory accesses experience an equivalent transceiver delay, but persons skilled in the art will recognize how to implement systems which have masters on more than one bus unit and memory devices on the transceiver bus as well as on primary bus units.

In general, each teaching of this invention which refers to a memory device can be practiced using a transceiver device and one or more memory devices on an attached primary bus unit. Other devices, generically referred to as peripheral devices, including disk controllers, video controllers or I/O devices can also be attached to either the transceiver bus or a primary bus unit, as

desired. Persons skilled in the art will recognize how to use a single primary bus unit or multiple primary bus units as needed with a transceiver bus in certain system designs.

The transceivers are quite simple in function. They 5 detect request packets on the transceiver bus and transmit them to their primary bus unit. If the request packet calls for a write to a device on a transceiver's primary bus unit, that transceiver keeps track of the access time and block size and forwards all data from the transceiver bus to the primary bus 10 unit during that time. The transceivers also watch their primary bus unit, forwarding any data that occurs there to the transceiver bus. The high speed of the buses means that the transceivers will need to be pipelined, and will require an additional one or two cycle delay for data to pass through the 15 transceiver in either direction. Access times stored in masters on the transceiver bus must be increased to account for transceiver delay but access times stored in slaves on a primary bus unit should not be modified.

Persons skilled in the art will recognize that a more 20 sophisticated transceiver can control transmissions to and from primary bus units. An additional control line, TrncvrRW can be bused to all devices on the transceiver bus, using that line in conjunction with the AddrValid line to indicate to all devices on the transceiver bus that the information on the data lines is: 1) 25 a request packet, 2) valid data to a slave, 3) valid data from a

slave, or 4) invalid data (or idle bus). Using this extra control line obviates the need for the transceivers to keep track of when data needs to be forwarded from its primary bus to the transceiver bus - all transceivers send all data from their primary bus to the transceiver bus whenever the control signal indicates condition 2) above. In a preferred implementation of this invention, if AddrValid and TrncvrRW are both low, there is no bus activity and the transceivers should remain in an idle state. A controller sending a request packet will drive AddrValid high, indicating to all devices on the transceiver bus that a request packet is being sent which each transceiver should forward to its primary bus unit. Each controller seeking to write to a slave should drive both AddrValid and TrncvrRW high, indicating valid data for a slave is present on the data lines. Each transceiver device will then transmit all data from the transceiver bus lines to each primary bus unit. Any controller expecting to receive information from a slave should also drive the TrncvrRW line high, but not drive AddrValid, thereby indicating to each transceiver to transmit any data coming from any slave on its primary local bus to the transceiver bus. A still more sophisticated transceiver would recognize signals addressed to or coming from its primary bus unit and transmit signals only at requested times.

An example of the physical mounting of the transceivers is shown in Figure 9. One important feature of this physical

arrangement is to integrate the bus of each transceiver 19 with the original bus of DRAMs or other devices 15, 16, 17 on the primary bus unit 66. The transceivers 19 have pins on two sides, and are preferably mounted flat on the primary bus unit with a first set of pins connected to primary bus 18. A second set of transceiver pins 20, preferably orthogonal to the first set of pins, are oriented to allow the transceiver 19 to be attached to the transceiver bus 65 in much the same way as the DRAMs were attached to the primary bus unit. The transceiver bus can be generally planar and in a different plane, preferably orthogonal to the plane of each primary bus unit. The transceiver bus can also be generally circular with primary bus units mounted perpendicular and tangential to the transceiver bus.

Using this two level scheme allows one to easily build a system that contains over 500 slaves (16 buses of 32 DRAMs each). Persons skilled in the art can modify the device ID scheme described above to accommodate more than 256 devices, for example by using a longer device ID or by using additional registers to hold some of the device ID. This scheme can be extended in yet a third dimension to make a second-order transceiver bus, connecting multiple transceiver buses by aligning transceiver bus units parallel to and on top of each other and busing corresponding signal lines through a suitable transceiver. Using such a second-order transceiver bus, one

could connect many thousands of slave devices into what is effectively a single bus.

Device Interface

5 The device interface to the high-speed bus can be

divided into three main parts. The first part is the electrical interface. This part includes the input receivers, bus drivers and clock generation circuitry. The second part contains the

10 address comparison circuitry and timing registers. This part takes the input request packet and determines if the request is

for this device, and if it is, starts the internal access and delivers the data to the pins at the correct time. The final

15 part, specifically for memory devices such as DRAMs, is the DRAM column access path. This part needs to provide bandwidth into and out of the DRAM sense amps greater than the bandwidth

provided by conventional DRAMs. The implementation of the

electrical interface and DRAM column access path are described in more detail in the following sections. Persons skilled in the

20 art recognize how to modify prior-art address comparison circuitry and prior-art register circuitry in order to practice

the present invention.

Electrical Interface - Input/Output Circuitry

A block diagram of the preferred input/output circuit

25 for address/data/control lines is shown in Figure 10. This

5 circuitry is particularly well-suited for use in DRAM devices but it can be used or modified by one skilled in the art for use in other devices connected to the bus of this invention. It consists of a set of input receivers 71, 72 and output driver 76 connected to input/output line 69 and pad 75 and circuitry to use the internal clock 73 and internal clock complement 74 to drive the input interface. The clocked input receivers take advantage of the synchronous nature of the bus. To further reduce the performance requirements for device input receivers, each device 10 pin, and thus each bus line, is connected to two clocked receivers, one to sample the even cycle inputs, the other to sample the odd cycle inputs. By thus de-multiplexing the input 70 at the pin, each clocked amplifier is given a full 2 ns cycle to amplify the bus low-voltage-swing signal into a full value CMOS logic signal. Persons skilled in the art will recognize 15 that additional clocked input receivers can be used within the teachings of this invention. For example, four input receivers could be connected to each device pin and clocked by a modified internal device clock to transfer sequential bits from the bus to 20 internal device circuits, allowing still higher external bus speeds or still longer settling times to amplify the bus low-voltage-swing signal into a full value CMOS logic signal.

25 The output drivers are quite simple, and consist of a single NMOS pulldown transistor 76. This transistor is sized so that under worst case conditions it can still sink the 50 mA

required by the bus. For 0.8 micron CMOS technology, the transistor will need to be about 200 microns long. Overall bus performance can be improved by using feedback techniques to control output transistor current so that the current through the device is roughly 50 mA under all operating conditions, although this is not absolutely necessary for proper bus operation. An example of one of many methods known to persons skilled in the art for using feedback techniques to control current is described in Hans Schumacher, et al., "CMOS Subnanosecond True-ECL Output Buffer," *J. Solid State Circuits*, Vol. 25 (1), pp. 150-154 (Feb. 1990). Controlling this current improves performance and reduces power dissipation. This output driver which can be operated at 500 MHz, can in turn be controlled by a suitable multiplexer with two or more (preferably four) inputs connected to other internal chip circuitry, all of which can be designed according to well known prior art.

The input receivers of every slave must be able to operate during every cycle to determine whether the signal on the bus is a valid request packet. This requirement leads to a number of constraints on the input circuitry. In addition to requiring small acquisition and resolution delays, the circuits must take little or no DC power, little AC power and inject very little current back into the input or reference lines. The standard clocked DRAM sense amp shown in Figure 11 satisfies all these requirements except the need for low input currents. When

5 this sense amp goes from sense to sample, the capacitance of the internal nodes 83 and 84 in Figure 11 is discharged through the reference line 68 and input 69, respectively. This particular current is small, but the sum of such currents from all the inputs into the reference lines summed over all devices can be reasonably large.

10 The fact that the sign of the current depends upon on the previous received data makes matters worse. One way to solve this problem is to divide the sample period into two phases. During the first phase, the inputs are shorted to a buffered version of the reference level (which may have an offset). During the second phase, the inputs are connected to the true inputs. This scheme does not remove the input current completely, since the input must still charge nodes 83 and 84 from the reference value to the current input value, but it does reduce the total charge required by about a factor of 10 (requiring only a 0.25V change rather than a 2.5V change). Persons skilled in the art will recognize that many other methods can be used to provide a clocked amplifier that will operate on 15 20 very low input currents.

25 One important part of the input/output circuitry generates an internal device clock based on early and late bus clocks. Controlling clock skew (the difference in clock timing between devices) is important in a system running with 2 ns cycles, thus the internal device clock is generated so the input

sampler and the output driver operate as close in time as possible to midway between the two bus clocks.

A block diagram of the internal device clock generating circuit is shown in Figure 12 and the corresponding timing diagram in Figure 13. The basic idea behind this circuit is relatively simple. A DC amplifier 102 is used to convert the small-swing bus clock into a full-swing CMOS signal. This signal is then fed into a variable delay line 103. The output of delay line 103 feeds three additional delay lines: 104 having a fixed delay; 105 having the same fixed delay plus a second variable delay; and 106 having the same fixed delay plus one half of the second variable delay. The outputs 107, 108 of the delay lines 104 and 105 drive clocked input receivers 101 and 111 connected to early and late bus clock inputs 100 and 110, respectively. These input receivers 101 and 111 have the same design as the receivers described above and shown in Fig. 11. Variable delay lines 103 and 105 are adjusted via feedback lines 116, 115 so that input receivers 101 and 111 sample the bus clocks just as they transition. Delay lines 103 and 105 are adjusted so that the falling edge 120 of output 107 precedes the falling edge 121 of the early bus clock, Clock1 53, by an amount of time 128 equal to the delay in input sampler 101. Delay line 108 is adjusted in the same way so that falling edge 122 precedes the falling edge 123 of late bus clock, Clock2 54, by the delay 128 in input sampler 111.

Since the outputs 107 and 108 are synchronized with the two bus clocks and the output 73 of the last delay line 106 is midway between outputs 107 and 108, that is, output 73 follows output 107 by the same amount of time 129 that output 73 precedes output 108, output 73 provides an internal device clock midway between the bus clocks. The falling edge 124 of internal device clock 73 precedes the time of actual input sampling 125 by one sampler delay. Note that this circuit organization automatically balances the delay in substantially all device input receivers 71 and 72 (Fig. 10), since outputs 107 and 108 are adjusted so the bus clocks are sampled by input receivers 101 and 111 just as the bus clocks transition.

In the preferred embodiment, two sets of these delay lines are used, one to generate the true value of the internal device clock 73, and the other to generate the complement 74 without adding any inverter delay. The dual circuit allows generation of truly complementary clocks, with extremely small skew. The complement internal device clock is used to clock the 'even' input receivers to sample at time 127, while the true internal device clock is used to clock the 'odd' input receivers to sample at time 125. The true and complement internal device clocks are also used to select which data is driven to the output drivers. The gate delay between the internal device clock and output circuits driving the bus is slightly greater than the corresponding delay for the input circuits, which means that the

new data always will be driven on the bus slightly after the old data has been sampled.

DRAM Column Access Modification

5 A block diagram of a conventional 4 MBit DRAM 130 is shown in Figure 15. The DRAM memory array is divided into a number of subarrays 150-157, for example, 8. Each subarray is divided into arrays 148, 149 of memory cells. Row address selection is performed by decoders 146. A column decoder 147A, 10 147B, including column sense amps on either side of the decoder, runs through the core of each subarray. These column sense amps can be set to precharge or latch the most-recently stored value, as described in detail above. Internal I/O lines connect each set of sense-amps, as gated by corresponding column decoders, to 15 input and output circuitry connected ultimately to the device pins. These internal I/O lines are used to drive the data from the selected bit lines to the data pins (some of pins 131-145), or to take the data from the pins and write the selected bit lines. Such a column access path organized by prior art 20 constraints does not have sufficient bandwidth to interface with a high speed bus. The method of this invention does not require changing the overall method used for column access, but does change implementation details. Many of these details have been implemented selectively in certain fast memory devices, but never 25 in conjunction with the bus architecture of this invention.

Running the internal I/O lines in the conventional way at high bus cycle rates is not possible. In the preferred method, several (preferably 4) bytes are read or written during each cycle and the column access path is modified to run at a lower rate (the inverse of the number of bytes accessed per cycle, preferably 1/4 of the bus cycle rate). Three different techniques are used to provide the additional internal I/O lines required and to supply data to memory cells at this rate. First, the number of I/O bit lines in each subarray running through the column decoder 147 is increased, for example, to 16, eight for each of the two columns of column sense amps and the column decoder selects one set of columns from the "top" half 148 of subarray 150 and one set of columns from the "bottom" half 149 during each cycle, where the column decoder selects one column sense amp per I/O bit line. Second, each column I/O line is divided into two halves, carrying data independently over separate internal I/O lines from the left half 147A and right half 147B of each subarray (dividing each subarray into quadrants) and the column decoder selects sense amps from each right and left half of the subarray, doubling the number of bits available at each cycle. Thus each column decode selection turns on n column sense amps, where n equals four (top left and right, bottom left and right quadrants) times the number of I/O lines in the bus to each subarray quadrant (8 lines each \times 4=32 lines in the preferred implementation). Finally, during each RAS cycle,

two different subarrays, e.g. 157 and 153, are accessed. This
doubles again the available number of I/O lines containing data.
Taken together, these changes increase the internal I/O bandwidth
by at least a factor of 8. Four internal buses are used to route
5 these internal I/O lines. Increasing the number of I/O lines and
then splitting them in the middle greatly reduces the capacitance
of each internal I/O line which in turn reduces the column access
time, increasing the column access bandwidth even further.

10 The multiple, gated input receivers described above
allow high speed input from the device pins onto the internal I/O
lines and ultimately into memory. The multiplexed output driver
described above is used to keep up with the data flow available
using these techniques. Control means are provided to select
whether information at the device pins should be treated as an
15 address, and therefore to be decoded, or input or output data to
be driven onto or read from the internal I/O lines.

10 Each subarray can access 32 bits per cycle, 16 bits
from the left subarray and 16 from the right subarray. With 8
I/O lines per sense-amplifier column and accessing two subarrays
20 at a time, the DRAM can provide 64 bits per cycle. This extra
I/O bandwidth is not needed for reads (and is probably not used),
but may be needed for writes. Availability of write bandwidth is
a more difficult problem than read bandwidth because over-writing
25 a value in a sense-amplifier may be a slow operation, depending
on how the sense amplifier is connected to the bit line. The

extra set of internal I/O lines provides some bandwidth margin for write operations.

Persons skilled in the art will recognize that many variations of the teachings of this invention can be practiced
5 that still fall within the claims of this invention which follow.

CLAIMS

What is claimed is:

1. A memory subsystem comprising
two memory devices connected in parallel to a bus,
said bus including a plurality of bus lines for
carrying substantially all address, data and control in-
formation needed by said memory devices,
said control information including device-select
information,
said bus containing substantially fewer bus lines than
the number of bits in a single address, and
said bus carrying device-select information without the
need for separate device-select lines connected directly to
individual memory devices.
- 15 2. The memory subsystem of claim 1 wherein said bus
contains at least 8 bus lines adapted to carry at least 16
address bits and at least 8 data bits.
- 20 3. The memory subsystem of claim 1 wherein said bus also
includes parallel lines for clock and power.
4. A system comprising
a memory subsystem of claim 1 wherein each bus of said
memory subsystem is connected to its own transceiver device,

a transceiver bus connecting said transceiver devices,

and

5 a means for transferring information between each of said buses of said memory subsystems and said transceiver bus, whereby memory subsystems may be integrated into a larger system having more memory than an individual memory subsystem.

10 5. The system of claim 4 having a plurality of memory

subsystems.

15 6. The system of claim 4 further comprising a master device connected to said transceiver bus.

20 7. The system of claim 6 wherein said master device is selected from the group consisting of a central processing unit, a floating point unit and a direct memory access unit.

25 8. The system of claim 4 further comprising a peripheral device connected to the transceiver bus, said peripheral device adapted for connection to other devices not on the bus.

25 9. The system of claim 8 wherein said peripheral device is selected from the group consisting of an I/O interface port, a video controller and a disk controller.

10. The system of claim 5 wherein said transceiver bus is in a different plane than the plane of the bus of each of said memory subsystems.

5

11. The system of claim 5 wherein the bus of each memory subsystem lies substantially in a subsystem bus plane and said transceiver bus lies substantially in a plane orthogonal to said subsystem bus plane.

10

12. The system of claim 4 having at least two transceiver buses, each transceiver bus having a plurality of memory subsystem buses connected through a first transceiver to said transceiver bus,

15

each of said transceiver buses being further connected to a second transceiver adapted to interface to a second-order transceiver bus, whereby each transceiver bus is connected through said second transceiver to form a second-order transceiver bus unit.

20

13. A semiconductor subsystem bus for interconnecting semiconductor devices comprising

a plurality of semiconductor devices connected in parallel to a bus, at least one of said semiconductor

devices being a memory device or a transceiver device which in turn is connected to a memory subsystem,

5 said bus including a plurality of bus lines for carrying substantially all address, data and control information needed by said semiconductor devices,

said control information including semiconductor device-select information,

10 said bus containing substantially fewer bus lines than the number of bits in a single address, and

15 said bus carrying device-select information without the need for separate device-select lines connected directly to individual semiconductor devices, and

at least one modifiable register in each of the semiconductor devices on said bus, said modifiable registers being accessible from said bus, whereby the subsystem can be 20 configured using signals transmitted on said bus.

14. The semiconductor subsystem bus of claim 13 wherein one type of modifiable register is an access-time register designed 25 to store a time delay after which a device may take some specified action on said bus.

15. The semiconductor subsystem bus of claim 13 further comprising a semiconductor device having at least two access-time 25 registers and

one of said access-time registers is permanently programmed to contain a fixed value and at least one of said access-time registers can be modified by information carried on said bus.

5 16. The semiconductor subsystem bus of claim 13 further comprising a memory device having at least one discrete memory section and also having a modifiable address register adapted to store memory address information which corresponds to each said discrete memory section.

10 17. The semiconductor subsystem bus of claim 16 wherein said memory address information comprises a pointer to said discrete memory section.

15 18. The semiconductor subsystem bus of claim 16 wherein said discrete memory section has a top and a bottom and said memory address information comprises pointers to said top and said bottom.

20 19. The semiconductor subsystem bus of claim 16 wherein said memory address information comprises a pointer to said discrete memory section and a range value indicating the size of said discrete memory section.

20. The semiconductor subsystem bus of claim 16 wherein
said address registers of each of said discrete memory sections
of each of said memory devices connected to said bus are set to
contain memory address information that is different for each
5 discrete memory section and such that the highest memory address
in each discrete memory section is one less than the lowest
memory address in another discrete memory section,

whereby memory may be organized into one or a small number
of contiguous memory blocks.

10

10

15

20

21. The semiconductor subsystem bus of claim 16 further
comprising a means for testing each of said discrete memory sec-
tions of each of said memory devices for proper function, and
for each non-functional discrete memory section, a
means for setting at least one address register which
corresponds to said discrete memory section to indicate that
said discrete memory section is non-functional,
for each functional discrete memory section, a means
for setting at least one address register which corresponds
to said discrete memory section to contain such
corresponding address information.

22. The semiconductor subsystem bus of claim 21 wherein
said address registers corresponding to said discrete memory

sections are set to provide one contiguous memory block within the subsystem.

23. The semiconductor subsystem bus of claim 13 wherein one of said modifiable registers is a device identification register which can be modified to contain a value unique to that semiconductor device.

10 24. The semiconductor subsystem bus of claim 23 wherein said device identification register is set to contain a unique value which is a function of the physical position of that semiconductor device either along said bus or in relationship to other semiconductor devices or said bus.

15 25. A bus subsystem comprising

two semiconductor devices connected in parallel to a bus, wherein one of said semiconductor devices is a master device,

20 said master device including a means for initiating bus transactions,

said bus including a plurality of bus lines for carrying substantially all address, data and control information needed by said devices,

25 said control information including device-select information,

5 said bus containing substantially fewer lines than the number of bits in a single address, and

10 said bus carrying device-select information without the need for separate device-select lines connected directly to individual devices on said bus, whereby said master device initiates bus transactions which transfer information between said semiconductor devices on said bus.

15 26. The bus subsystem of claim 25 wherein one of said

20 semiconductor devices is a memory device connected to said bus, said memory device having at least one discrete memory section and also having a modifiable address register adapted to store memory address information which corresponds to each said discrete memory section.

25 27. The bus subsystem of claim 26 wherein one of said

30 semiconductor devices comprises a transceiver device connected in parallel to said bus and connected in parallel to a memory device on a bus other than said bus.

35 28. The bus subsystem of claim 26 further including a means

40 for said master device to request said memory device to prepare for a bus transaction by sending a request packet along said bus, said memory device and said master device each having a device-internal means to prepare to begin said bus transaction during a

device-internal phase and further having a bus access means to effect said bus transaction during a bus access phase, said request packet including

5 a sequence of bytes containing address and control information,

said control information including information about the requested bus transaction and about the access time, which corresponds to a number of bus cycles, which needs to intervene before beginning said bus-access phase, and

10 said address information pointing to at least one memory location within one of said discrete memory sections of said memory device.

29. The bus subsystem of claim 28 wherein said memory device includes a means to read said control information and initiate said device-internal means at a time so as to complete said device-internal phase within said access time and begin said bus access phase after said number of bus cycles.

20 30. The bus subsystem of claim 28 wherein said control information comprises an op code.

31. The bus subsystem of claim 30 wherein said memory device includes sense amplifiers adapted to hold a bit of information or to precharge after a selected time and a means to

transfer a data block during a data block transfer either reading data from said memory device or writing data into said memory device, and

5 wherein said op code instructs said memory device to activate a response means, said response means including a means to

10 initiate a data block transfer,

15 select the size of said data block,

20 select the time to initiate said data block transfer,

25 access a control register, including reading from or writing to said control register,

30 precharge said sense amplifiers after each of said data block transfers is complete,

35 hold a bit of information in each of said sense amplifiers after each of said data block transfers is complete, or

40 select normal or page-mode access.

32. The bus subsystem of claim 31 wherein said data block

45 transfer comprises a read from or a write to memory within a single memory device.

33. The bus subsystem of claim 28 further comprising a means for said master device to send control information to a specific one of said semiconductor devices on said bus by

including in said request packet a device identification number unique to said semiconductor device.

34. The bus subsystem of claim 28 further comprising a
5 means for said master device to send control information to a selected one of said discrete memory portions by including in said request packet a specific memory address.

10 35. The bus subsystem of claim 28 further comprising a means for said master device to send control information to substantially all semiconductor devices on said bus by including in said request packet a special device identification number which is recognized by said semiconductor devices.

15 36. The bus subsystem of claim 28 wherein said control information specifies directly or indirectly the number of bus cycles for said master device and said memory device to wait before beginning said bus access phase.

20 37. The bus subsystem of claim 36 wherein, for a data block transfer, said master device and said memory device use the same access time and same data block size regardless of whether said data block transfer is a read or write operation.

38. The bus subsystem of claim 28 wherein said control information further includes a block-size value that encodes and specifies the size of the block of data to be transferred.

5 39. The bus subsystem of claim 38 wherein said block-size value is encoded as a linear value for relatively small block sizes values and is encoded as a logarithmic value for relatively larger block sizes.

10 40. The bus subsystem of claim 38 wherein said block-size value is encoded using four bits, and where the encoded value is

	<u>Encoded Value</u>	<u>Block Size (Bytes)</u>

	10	32
	11	64
	12	128
	13	256
	14	512
	15	1024

41. The bus subsystem of claim 26 wherein said memory device is a DRAM device containing a plurality of sense amplifiers,

35

a means to hold said sense amplifiers in an unmodified state after a read or write operation, leaving the device in page mode,

5 a means to precharge said sense amplifiers and

a means for selecting whether to precharge said sense amplifiers or to hold said sense amplifiers in an unmodified state.

42. The bus subsystem of claim 28 wherein said request

10 packet comprises an even number of bytes.

43. The bus subsystem of claim 28 further including a means for generating and controlling a plurality of bus cycles, during which said bus carries said address, data and control information, and wherein alternate said bus cycles are designated odd cycles and even cycles, respectively, and wherein said 15 request packet begins only on an even cycle.

44. The bus subsystem of claim 28 further including a means

20 for generating ECC information corresponding to a block of data and a means for using said ECC information to correct errors in storing or reading said block of data, wherein said ECC information may be stored separately from said block of data.

45. The bus subsystem of claim 44 further comprising at least two of said memory devices wherein said ECC information and said corresponding block of data are stored in a first and a second said memory device, respectively, and said master device 5 includes a means to write or read said block of data with error correction by sending separate ones of said request packets for said ECC information and for said corresponding block of data.

46. A bus subsystem comprising
10 a memory device and a master device connected in parallel on a bus,

a means for said master device to send a request packet and initiate a bus transaction and

15 a means for said master device to keep track of current and pending bus transactions,

said bus including a plurality of bus lines for carrying substantially all address, data and control 20 information needed by said memory devices,

said bus containing substantially fewer lines than the number of bits in a single address, and

25 said bus carrying device-select information without the need for separate device-select lines connected directly to individual devices on said bus, whereby said master device initiates bus transactions which transfer information between devices on said bus and collisions on said bus are

avoided because said master device avoids initiating bus transactions which would conflict with current or pending bus transactions.

5 47. The bus subsystem of claim 46 having at least two of said master devices and including

10 a collision detecting means whereby a first said master device sending a first said request packet can detect a second said master device sending one of said colliding request packets, where one of said said colliding request packet may be sent simultaneous with the initial sending of or overlapping the sending of said first request packet, and

15 an arbitration means whereby said first and said second master devices select a priority order in which each of said master devices will be allowed to access said bus sequentially.

20 48. The bus subsystem of claim 47 wherein each of said master devices has a master ID number and each of said request packets includes a master ID position which is a predetermined number of bits in a predetermined position in said request packet, and wherein said collision detection means comprises

25 a means included in each master device for sending a request packet including said master ID number of said

master device in said master ID position of said request packet and

5 a means to detect a collision and invoke said arbitration means if any master device detects any other master ID number in said master ID position.

49. The bus subsystem of claim 47 wherein each of said master devices includes

a means for sending a request packet,

10 a means for driving a selected bus line or lines during at least one selected bus cycle while said request packet is being sent,

15 a means for monitoring said selected bus line or lines to see if a said master device is sending a colliding request packet and

a means for informing all other master devices that a collision has occurred and for invoking said arbitration means.

20 50. The bus subsystem of claim 47 wherein each of said master devices includes

a means, when sending a request packet, to drive a selected bus line or lines with a certain current during at least one selected bus cycle,

10 a means for monitoring said selected bus line or lines
for a greater than normal current to see if another master
device is driving that line or lines,

5 a means for detecting said greater than normal current,
and

15 a means for informing all said master devices that a
collision has occurred and for invoking said arbitration
means.

20 51. The bus subsystem of claim 47 wherein said arbitration
means comprises

a means for initiating an arbitration cycle,
a means for allocating a single bus line to each master
device during at least one selected bus cycle relative to
15 the start of said arbitration cycle,

a means for allocating each master device to a single
bus line during one of said selected bus cycles if there are
more master devices than available bus lines,

20 a means for each of said master devices which sent a
colliding request packet to drive said bus line allocated to
said master device during said selected bus cycle, and

a means in at least one of said master devices for
storing information about which master devices sent a
colliding request packet,

whereby said master devices can monitor selected bus lines during said arbitration cycle and identify each said master device which sent a colliding request packet.

5 52. The bus subsystem of claim 47 wherein said arbitration means comprises

a means included in a first one of said master devices which sent colliding request packets for identifying each of said master devices which sent colliding request packets,

10 a means for assigning a priority to each said master device which sent a colliding request packet, and

a means for allowing each said master device which sent a colliding request packet to access the bus sequentially according to that priority.

15 53. The bus subsystem of claim 52 wherein said priority is based on the physical location of each of said master devices.

54. The bus subsystem of claim 52 wherein said priority is 20 based on said master ID number of said master devices.

25 55. The bus subsystem of claim 52 wherein each of said master devices includes a means, when sending a colliding request packet, for deciding which master device can send the next request packet in what order or at what time, whereby no master

device may send a new request packet until responses to each pending request packet have been completed or scheduled.

5 56. A bus subsystem comprising
a plurality of semiconductor devices connected in parallel to a bus,

10 said bus including a plurality of bus lines for carrying substantially all address, data and control information needed by said semiconductor devices,

15 said control information including device-select information,

20 said bus containing substantially fewer lines than the number of bits in a single address,

25 said bus carrying said device-select information without the need for separate device-select lines connected directly to individual semiconductor devices,

30 said semiconductor devices including a reset means having an input and an output, the output of the reset means of one semiconductor device being connected to the input of the reset means of the next semiconductor device in series.

57. The bus subsystem of claim 56 further including system reset means comprising

35 a means for generating a first and a second reset signal,

a means for passing said first reset signal to a first of said semiconductor devices and then to subsequent ones of said semiconductor devices in series and

5 a means for passing a second reset signal to said first semiconductor device and then to said subsequent semiconductor devices in series,

said bus subsystem including one of said semiconductor devices containing

10 a device identification register adapted to contain a number unique to said semiconductor device within said bus subsystem,

a device identification register setting means, and

15 a device reset means for resetting said semiconductor device to some desired, known reset state in response to said first reset signal and for setting said device identification register in response to said second reset signal,

20 whereby said bus subsystem can be reset to a known reset state with a unique device identification value in said device identification register of each of said semiconductor devices.

58. The bus subsystem of claim 57 wherein said desired, known reset state is where all registers in the semiconductor 25 device are cleared and the state machines are reset.

59. The bus subsystem of claim 57 wherein said device identification register setting means comprises

5 a means for detecting said second reset signal,

10 a means for reading a device identification number from said bus lines at a specific time relative to said second reset signal and

15 a means for storing said device identification number in said device identification register of said semiconductor device.

10 60. The bus subsystem of claim 57 wherein said second reset signal comprises multiple pulse sequences and wherein said device identification setting means includes

15 a means for interpreting said pulse sequences as a device identification number and

20 a means for storing said device identification number in said device identification register of said semiconductor device.

20 61. The bus subsystem of claim 57 wherein said device reset means comprises an n -stage shift register capable of storing n -bit values, wherein said device reset means interprets a specific value in said shift register as said first reset signal and

interprets a specific value in said shift register as said second reset signal.

62. The bus subsystem of claim 57 wherein one of said 5 semiconductor devices is a master device, said master device including a means for generating said first and said second reset signals.

63. The bus subsystem of claim 57 wherein one of said 10 semiconductor devices is a master device, said master device including

a master ID register,
a means for assigning a master ID number to said master device and
15 a means for storing said master ID number in said master ID register.

64. The bus subsystem of claim 63 further comprising a second one of said master devices, and a means for a first one of 20 said master devices to assign a master ID number to substantially all other said master devices, whereby said first master device assigns one of said master ID numbers to each of said master devices on said bus subsystem and each said master device stores said assigned master ID number in said master ID register.

25

65. The bus subsystem of claim 57 wherein one of said semiconductor devices includes a device-type register adapted to contain an identifier characteristic of that type of semiconductor device, and one or more modifiable registers, at 5 least one of which is an access-time register adapted for storing access times.

66. The bus subsystem of claim 65 wherein one of said semiconductor devices is a master device having
10 a means for selecting a semiconductor device,
a means for reading said device-type register of said selected semiconductor device,
a means for determining the device type of said selected semiconductor device,
15 a means for determining access-time values appropriate for said selected semiconductor device and for storing said access-time values in said access-time registers of said selected semiconductor device, and
a means for selecting and storing other values
20 appropriate for said selected semiconductor device in corresponding registers of said selected semiconductor device,
25 whereby said master device can select a semiconductor device, determine what type it is, and set said access-time and other registers to contain appropriate values..

67. The bus subsystem of claim 66 further comprising a memory device having at least one discrete memory section and at least one modifiable address register adapted to store memory address information which corresponds to each of said discrete memory sections, and

5 said master device further comprising a means for selecting and testing each of said discrete memory sections and a means for storing address information in said address registers corresponding to each of said discrete memory sections, whereby said master device can test all said discrete memory sections and assign unique address values thereto.

5 said bus carrying device-select information without the
need for separate device-select lines connected directly to
individual semiconductor devices,

5 wherein all of said bus data lines are terminated
transmission lines and all of said address, data and control
information is carried on said bus data lines as a
sequential series of bits in the form of low-voltage-swing
signals.

10 69. The bus subsystem of claim 68 further comprising a

10 semiconductor device including a current-mode driver connected to
drive one of said bus data lines.

15 70. The bus subsystem of claim 69 further comprising a

15 semiconductor device having a means to measure the voltage of
said low-voltage-swing signals on a selected one of said bus data
lines, whereby said semiconductor device can determine whether
zero, one, or more than one of said current-mode drivers are
driving said selected bus data line.

20 71. The bus subsystem of claim 70 further comprising a
semiconductor device having

 a plurality of input receivers connected to one of said
bus data lines, and

5 a selection means for selecting said input receivers one by one to sense and store, one at a time, the bits of said sequential series of bits.

10 5 72. The bus subsystem of claim 70 further comprising a semiconductor device having two input receivers connected to one of said bus data lines.

15 10 73. A bus subsystem comprising

15 15 two semiconductor devices connected in parallel to a bus having a first and a second end, said bus including a bus clock line, said bus clock line having first and second ends corresponding to said first and second ends of said bus, respectively,

20 20 15 a clock generator connected to said first end of said bus clock line to generate early bus clock signals with a normal rise time, and

25 25 20 signal return means at said second end of said bus clock line to return said early bus clock signals to said first end of said bus as corresponding late bus clock signals,

25 25 whereby each of said early bus clock signals will propagate from said clock generator along said clock line starting from said first end to said second end of said bus and then return at a later time to said first end of said

bus as a corresponding late bus clock signal, whereby each semiconductor device on said bus can detect said early bus clock signals and said corresponding late bus clock signals.

5 74. The bus subsystem of claim 73 further comprising a first and a second said bus clock line having first and second ends at said first and said second ends of said bus, respectively, wherein said signal return means directly connects said second ends of said first and said second bus clock lines whereby each of said early bus clock signals will propagate from said clock generator at said first end of said bus along said first bus clock line to said second end of said bus and then return on said second bus clock line to said first end of said bus as one of said corresponding late bus clock signals.

10 75. The bus subsystem of claim 73 wherein said signal return means comprises said first bus clock line without a line terminator at said second end thereof whereby each of said early bus clock signals reaching said second end of said first bus clock line will be reflected back along said first bus clock line as said corresponding late bus clock signals.

76. The bus subsystem of claim 73 further comprising
a means for operating said bus in bus cycles timed to
have a certain bus cycle frequency and a corresponding bus
cycle period and

5 a means for operating said clock generator with a
period of twice the bus cycle period.

77. The bus subsystem of claim 76 wherein said bus cycle
frequency is greater than approximately 50 MHz and less than or
10 equal to approximately 500 MHz.

78. The bus subsystem of claim 73 further including a
semiconductor device having an internal device clock generating
means to derive the midpoint time between said early and
15 corresponding late bus clock signals and to generate an internal
device clock synchronized to said midpoint time.

79. The bus subsystem of claim 73 further including a
semiconductor device having a low-skew clock generator circuit
20 comprising

a first delay line having an input, an output and a
basic delay and means for synchronizing the output of said
first delay line with said early bus clock signal,

25 a second delay line having said basic delay plus a
variable delay, said second delay line having an output and

5 a means for synchronizing the output of said second delay line with said late bus clock signal, and

10 a third delay line having a third delay and a means to set said third delay midway between the delays of said first and second delay lines, said third delay line having an output which provides an internal device clock signal synchronized to a time halfway between said early and said late bus clock signals.

15 80. The bus subsystem of claim 73 wherein said early and said late bus clock signals are low-voltage-swing signals that transition cyclically between low and high logical values, and further including a semiconductor device having a low-skew clock generator circuit comprising

20 a DC amplifier to convert said early and said late bus clock signals into full-swing logic signals,

25 a first variable delay line having a first variable delay and an input and an output, the input of said first variable delay line being connected to said DC amplifier

30 a first, a second and a third additional delay line, each having an input and an output, the input of each of said additional delay lines being connected to the output of said first delay line,

35 said first additional delay line having a fixed

40 delay,

said second additional delay line having said fixed delay plus a second variable delay, and

said third additional delay line having said fixed delay plus one half of said second variable delay,

a first clocked input receiver connected to sample said early bus clock signal and gated by said output of said first additional delay line,

a means for adjusting said first variable delay so said first clocked input receiver samples said early bus clock signal just as said early bus clock signal transitions,

a second clocked input receiver connected to sample said late bus clock signal and gated by said output of said second additional delay line,

a means for adjusting said second variable delay so said second clocked input receiver samples said late bus clock signal just as said late bus clock signal transitions,

whereby said output of said third additional delay line is synchronized to a time halfway between said outputs of said first and said second additional delay lines, and said output of said third additional delay line provides an internal device clock signal.

81. The bus subsystem of claim 80 further comprising a semiconductor device having

a first one of said low-skew clock generator circuits which generates a "true" internal device clock signal and

a second one of said low-skew clock generator circuits connected to generate a "complement" internal device clock signal synchronized with but opposite in logical value to said "true" internal device clock signal.

82. A DRAM device designed to be connected to an external

bus having a plurality of bus lines for carrying substantially all address, data and control information needed by said DRAM device as a sequential series of bits, said control information including device-select information, said external bus containing substantially fewer said bus lines than the number of bits in a single address, and said bus carrying device-select information without the need for separate device-select lines connected directly to said DRAM device, said DRAM device comprising

an array of memory cells connected in rows and columns, each of said memory cells adapted to store one of said bits, a row address selection means for selecting one of said rows,

a column sense amp connected to each of said columns, each of said column sense amps adapted to latch one of said

bits as a binary logical value or to precharge to a selected state,

5 a column decoding means connected to each of said column sense amps for selecting a plurality of said column sense amps for inputting one of said bits to or outputting one of said bits from said memory cells,

10 an internal I/O bus having a plurality of internal I/O lines wherein each of said internal I/O lines is connected to a plurality of said column sense amps, and

15 a plurality of bus connection means designed to connect said internal I/O lines to said external bus,

20 whereby a selected bit of said sequential series of bits can be transferred from said external bus to a selected one of said memory cells or said bit contained in a selected one of said memory cells can be transferred to said external bus.

25 83. The DRAM device of claim 82 further comprising
an output driver connected to one said bus connection
means,

30 an output multiplexer having an output connected to said output driver and a plurality of inputs, each of said inputs being connected to one of said internal I/O lines,
and

5 a control means to select whether said output driver can drive said external bus,

5 whereby a plurality of memory cells are selected using said row address selection means and said column decoding means and a plurality of bits contained in said plurality of memory cells are output through said column sense amps to said internal I/O bus to said output multiplexer to said output driver to said external bus.

10 84. The DRAM device of claim 82 further comprising

10 a plurality of input receivers connected to one of said bus data lines and to said internal I/O bus,

15 a selection means for selecting said input receivers one by one to sense and store, one at a time, the bits of said sequential series of bits, and

20 a control means to select whether an input receiver can drive said internal I/O bus, whereby a bit of said sequential series of bits is input from said external bus through one of said input receivers to one of said internal I/O lines to one of said column sense amps to one of said memory cells.

85. The DRAM device of claim 82 further comprising
a first and a second half-array of said memory cells
wherein each said row of said array of said memory cells is
subdivided into two parts,

5 a first and a second one of said internal I/O buses
connected to said column sense amps in said first and said
second half-arrays, respectively, and

10 a column decoder means to gate selected ones of said
column sense amps connected to said memory cells in a
selected row of said first and said second half-arrays
simultaneously.

15 86. The DRAM device of claim 85 wherein said column decoder
means selects sixteen column sense amps at a time.

20 87. The DRAM device of claim 82 wherein said external bus
operates at a certain speed and wherein said DRAM device includes
four of said internal I/O buses, each of which operates at one-
fourth the speed of said external bus.

88. The DRAM device of claim 82 further comprising
a means for precharging one of said column sense amps
to a precharged state from which a binary logical value can
quickly be loaded into said column sense amp,

if said column sense amp contains a binary logical value, a means for latching the logical value currently contained in said column sense amp and

5 a means for instructing said DRAM device to precharge said column sense amp or latch said binary logical value in said column sense amp.

89. The DRAM device of claim 88 further comprising a means for instructing said DRAM device to precharge said column sense amp without further instruction whenever said row address 10 selection means selects a different one of said rows.

90. The DRAM device of claim 88 further comprising a means for instructing said DRAM device to precharge said column sense amp without further instruction at a first or a second 15 preselected time after latching the latest said binary logical value, said first preselected time being long enough for said DRAM to latch said binary logical value into said column sense amp and transfer said binary logical value into memory or onto one of said internal I/O lines, and said second preselected time 20 being a variable which can be stored in said DRAM device whereby said DRAM can latch a binary logical value into said column sense amp for transferring said binary logical value into or out of a selected said memory cell, then precharge to allow a faster 25 subsequent read or write.

91. A package containing

a semiconductor die having a side, circuitry and a plurality of connecting areas positioned along or near said side, spaced at a selected pitch and connected to said circuitry,

5 said package comprising a plurality of bus connecting means for connecting to a plurality of external bus lines, each of said external bus lines corresponding to one of said connecting areas, each of said bus connecting means being positioned on a first side of said package, connected to one said external bus line and to said corresponding connecting area on said semiconductor die, and

10 15 spaced at a pitch substantially identical to said selected pitch of said connecting areas, whereby each of said external bus lines can be connected to said corresponding connecting area on said semiconductor die by bus connection means positioned along a single side of said package.

20 25 92. The package of claim 91 further comprising a plurality of said bus connecting means wherein each of said bus connecting means includes

a pin adapted for connection to one of said external bus lines and

5 a wire connecting said pin to one of said connecting areas on said semiconductor die,

10 said wire having an effective lead length less than about 4 millimeters and wherein the effective lead length of said wire of each of said bus connection means for said package is approximately equal.

15 93. A plurality of packages of claim 91 wherein at least two of said semiconductor die are memory devices, each of said packages being generally flat, having a top and a bottom, and wherein

20 said packages are physically secured adjacent and parallel to each other in a stack,

25 where a first one of said packages is adjacent to a second one of said packages in said stack, said top of said first package is substantially aligned with said bottom of said second package, and

30 said bus connecting means of each of said packages are substantially aligned and are lying substantially in a plane.

35 94. The plurality of packages of claim 93 further comprising a plurality of stacks wherein each of said bus connecting means can be electrically connected to corresponding said bus connecting means in each of said stacks.

95. A semiconductor device capable of use in a semiconductor bus architecture including a plurality of semiconductor devices connected in parallel to a bus wherein said bus includes a plurality of bus lines for carrying substantially all address, 5 data, control and device-select information needed by said semiconductor device for communication with substantially every other semiconductor device connected to said bus, and has substantially fewer bus lines than the number of bits in a single address, and carries device-select information for said semiconductor device without the need for a separate device-select line connected directly to said individual semiconductor device, said semiconductor device comprising 10 connection means adapted to connect said semiconductor device to said bus, and 15 at least one modifiable identification register accessible to said bus through said connection means, whereby data may be transmitted to said register via said bus and enable said device thereafter to be uniquely identified.

20

96. The semiconductor device of claim 95 wherein said semiconductor device is a memory device which connects substantially only to said bus and sends and receives substantially all address, data and control information over said bus. 25

97. A semiconductor device capable of use in a semi-

conductor bus architecture including a plurality of semiconductor devices connected in parallel to a bus wherein said bus includes a plurality of bus lines for carrying substantially all address, data, control and device-select information needed by said semiconductor device for communication with substantially every other semiconductor device connected to said bus, and has substantially fewer bus lines than the number of bits in a single address, and carries device-select information for said semiconductor device without the need for a separate device-select line connected directly to said individual semiconductor device, said semiconductor device comprising

connection means adapted to connect said semiconductor device to said bus, and

15 at least one modifiable register to hold device address information, said modifiable register accessible to said bus through said connection means, whereby data may be transmitted to said register via said bus which 20 enables said device thereafter to respond to a predetermined range of addresses.

98. The semiconductor device of claim 97 wherein said

semiconductor device is a memory device which connects substantially only to said bus and sends and receives

substantially all address, data and control information over said bus.

99. The semiconductor device of claim 98 wherein said
5 memory device has at least one discrete memory section and also
has at least one modifiable address register adapted to store
memory address information which corresponds to each said
discrete memory section.

100. The semiconductor device of claim 99 wherein said
10 memory address information comprises a pointer to said discrete
memory section.

101. The semiconductor device of claim 100 wherein said
15 discrete memory section has a top and a bottom and said memory
address information comprises pointers to said top and said
bottom.

102. The semiconductor device of claim 100 wherein said
20 memory address information comprises
a pointer to said discrete memory section and
a range value indicating the size of said discrete
memory section.

103. A semiconductor device capable of use in a semi-

conductor bus architecture including a plurality of semiconductor devices connected in parallel to a bus wherein said bus includes a plurality of bus lines for carrying substantially all address, 5 data and control information needed by said semiconductor device for communication with substantially every other semiconductor device connected to said bus, and has substantially fewer bus lines than the number of bits in a single address, said semiconductor device comprising

10 connection means adapted to connect said semiconductor device to said bus, and

15 at least one modifiable access-time register accessible to said bus through said connection means, whereby data may be transmitted to said register via said bus which establishes a predetermined amount of time that said semiconductor device thereafter must wait before using said bus in response to a request.

104. The semiconductor device of claim 103 wherein said

20 semiconductor device is a memory device which connects substantially only to said bus and sends and receives substantially all address, data and control information over said bus.

105. The semiconductor device of claim 103 further comprising at least two access-time registers and one of said access-time registers is permanently programmed to contain a fixed value and at least one of said access-time registers can be modified by information carried on said bus.

106. A semiconductor device capable of use in a semiconductor bus architecture including a plurality of semiconductor devices connected in parallel to a bus wherein said bus includes a plurality of bus lines for carrying substantially all address, data, control and device-select information needed by said semiconductor device for communication with substantially every other semiconductor device connected to said bus, and has substantially fewer bus lines than the number of bits in a single address, and carries device-select information for said semiconductor device without the need for a separate device-select line connected directly to said individual semiconductor device, and wherein each said bus line is a terminated transmission line, said semiconductor device comprising connection means adapted to connect said semiconductor device to said bus, and a bus line driver capable of producing a low-voltage-swing signal on one of said terminated transmission lines.

107. The semiconductor device of claim 106 wherein said semiconductor device is a memory device which connects substantially only to said bus and sends and receives substantially all address, data and control information over said bus.

5

108. A semiconductor device capable of use in a semiconductor bus architecture including a plurality of semiconductor devices connected in parallel to a bus wherein said bus includes a plurality of bus lines for carrying substantially all address, data, control and device-select information needed by said semiconductor device for communication with substantially every other semiconductor device connected to said bus, and has substantially fewer bus lines than the number of bits in a single address, and carries device-select information for said semiconductor device without the need for a separate device-select line connected directly to said individual semiconductor device, said bus further including at least one bus clock line for carrying early and late bus clock signals, said semiconductor device comprising

15

connection means adapted to connect said semiconductor device to said bus, and

20

an internal device clock generating means which generates an internal device clock synchronized to a time halfway between said early and said late bus clock signals.

109. The semiconductor device of claim 108 wherein said bus further includes a first and a second one of said bus clock lines, said first bus clock line carries said early bus clock signal and said second bus clock line carries said late bus clock signal, said semiconductor device further comprising a means to detect said early bus clock signal on said first bus clock line and a means to detect said late bus clock signal on said second bus clock line.

10 110. The semiconductor device of claim 109 wherein said semiconductor device is a memory device which connects substantially only to said bus and sends and receives substantially all address, data and control information over said bus.

15 111. A semiconductor device capable of use in a semiconductor bus architecture including a plurality of semiconductor devices connected in parallel to a bus wherein said bus includes a plurality of bus lines for carrying as a sequential series of bits substantially all address, data, control and device-select 20 information needed by said semiconductor device for communication with substantially every other semiconductor device connected to said bus, and has substantially fewer bus lines than the number of bits in a single address, and carries device-select 25 information for said semiconductor device without the need for a

separate device-select line connected directly to said individual semiconductor device, said semiconductor device comprising.

5 connection means adapted to connect said semiconductor device to said bus,

a plurality of input receivers connected to one of said bus data lines and

10 a selection means for selecting said input receivers one by one to sense and store, one at a time, the bits of said sequential series of bits.

15 112. The semiconductor device of claim 111 wherein said semiconductor device is a memory device which connects substantially only to said bus and sends and receives substantially all address, data and control information over said bus.

20 113. The semiconductor device of claim 112 wherein two input receivers are connected to one of said bus lines.

25 114. A semiconductor device capable of use in an architecture for a semiconductor system bus including a plurality of semiconductor devices connected in parallel to a bus wherein said bus system includes a plurality of bus lines for carrying substantially all address, data, control and device-select information needed by said semiconductor device for communication

with substantially every other semiconductor device connected to said system bus, and has substantially fewer bus lines than the number of bits in a single address, and carries device-select information for said semiconductor device without the need for a 5 separate device-select line connected directly to said individual semiconductor device, said semiconductor device comprising connection means adapted to connect said semiconductor device to said system bus,

10 an internal input/output bus within said semiconductor device having more lines than said system bus, and a means for multiplexing the lines of said internal bus to the lines of said system bus, whereby said system bus can run at a higher speed than said internal bus.

15 115. The semiconductor device of claim 114 wherein said semiconductor device is a memory device which connects substantially only to said system bus and sends and receives substantially all address, data and control information over said system bus.

20 116. A semiconductor device capable of use in an architecture for a semiconductor system bus including a plurality of semiconductor devices connected in parallel to a bus wherein said system bus includes a plurality of bus lines for carrying substantially all address, data, control and device-select 25

information needed by said semiconductor device for communication with substantially every other semiconductor device connected to said system bus, and has substantially fewer bus lines than the number of bits in a single address, and carries device-select information for said semiconductor device without the need for a separate device-select line connected directly to said individual semiconductor device, said semiconductor device comprising connection means adapted to connect said semiconductor device to said system bus,

10 an internal input/output bus within said semiconductor device having more lines than said system bus,

15 a means for multiplexing the lines of said internal bus to the lines of said system bus, whereby said system bus can run at a higher speed than said internal bus, and

20 at least one modifiable identification register accessible to said system bus through said connection means, whereby data may be transmitted to said register via said system bus and which enables said device thereafter to be uniquely identified.

25 117. The semiconductor device of claim 116 wherein said semiconductor device is a memory device which connects substantially only to said system bus and sends and receives substantially all address, data and control information over said system bus.

118. A semiconductor device capable of use in an
architecture for a semiconductor system bus including a plurality
of semiconductor devices connected in parallel to a bus wherein
said system bus includes a plurality of bus lines for carrying
substantially all address, data, control and device-select
information needed by said semiconductor device for communication
with substantially every other semiconductor device connected to
said system bus, and has substantially fewer bus lines than the
number of bits in a single address, and carries device-select
information for said semiconductor device without the need for a
separate device-select line connected directly to said individual
semiconductor device, said semiconductor device comprising
connection means adapted to connect said semiconductor
device to said system bus,

15 an internal input/output bus within said semiconductor
device having more lines than said system bus,
a means for multiplexing the lines of said internal bus
to the lines of said system bus, whereby said system bus can
run at a higher speed than said internal bus, and
20 at least one modifiable register to hold device address
information, said modifiable register accessible to said
system bus through said connection means, whereby data may
be transmitted to said register via said system bus which
enables said device thereafter to respond to a predetermined
range of addresses.

119. The semiconductor device of claim 118 wherein said semiconductor device is a memory device which connects substantially only to said system bus and sends and receives substantially all address, data and control information over said system bus.

5 120. The semiconductor device of claim 119 wherein said memory device has at least one discrete memory section and also has at least one modifiable address register adapted to store 10 memory address information which corresponds to each said discrete memory section.

15 121. A semiconductor device capable of use in an architecture for a semiconductor system bus including a plurality of semiconductor devices connected in parallel to a bus wherein said system bus includes a plurality of bus lines for carrying substantially all address, data and control information needed by 20 said semiconductor device for communication with substantially every other semiconductor device connected to said system bus, and has substantially fewer bus lines than the number of bits in a single address, said semiconductor device comprising connection means adapted to connect said semiconductor device to said system bus,

25 an internal input/output bus within said semiconductor device having more lines than said system bus,

a means for multiplexing the lines of said internal bus to the lines of said system bus, whereby said system bus can run at a higher speed than said internal bus, and at least one modifiable access-time register accessible to said system bus through said connection means, whereby data may be transmitted to said register via said system bus which establishes a predetermined amount of time that said semiconductor device thereafter must wait before using said system bus in response to a request.

122. The semiconductor device of claim 121 wherein said semiconductor device is a memory device which connects substantially only to said system bus and sends and receives substantially all address, data and control information over said system bus.

123. The semiconductor device of claim 121 further comprising at least two access-time registers and one of said access-time registers is permanently programmed to contain a fixed value and at least one of said access-time registers can be modified by information carried on said system bus.

124. A semiconductor device capable of use in a semi-conductor bus architecture including a plurality of semiconductor devices connected in parallel to a bus wherein said bus includes

a plurality of bus lines for carrying substantially all address, data, control and device-select information needed by said semiconductor device for communication with substantially every other semiconductor device connected to said bus, and has substantially fewer bus lines than the number of bits in a single address, and carries device-select information for said semiconductor device without the need for a separate device-select line connected directly to said individual semiconductor device, wherein said address, data, control and device-select information is carried over said bus in the form of request packets and bus transactions, said semiconductor device comprising

connection means adapted to connect said semiconductor device to said bus,

a means to receive said request packets over said bus, a means to decode information in said request packets,

and

a means to respond to said information in said request packets.

20

125. The semiconductor device of claim 124 wherein said means to decode information in said request packet further comprises

a means to identify and decode said control information in said request packet,

a means to identify and decode said device-select
information in said request packet,
a means to identify and decode said address information
in said request packet and
5 a means to determine whether said control information
or said address information instructs said semiconductor
device to begin a response.

10 126. The semiconductor device of claim 124 wherein each of
said bus transactions is carried out in response to said address
and said control information in one of said request packets, and
wherein said means to identify and decode information in said
request packets includes a means to identify a sequence of bytes
on said bus as one of said request packets containing said
address and said control information, said control information
including information about the type of said bus transaction
15 being requested and the access time which needs to intervene
before beginning said bus transaction over said bus and said
address and said control information includes device-select
information instructing one or more said semiconductor devices to
20 respond to said address and said control information.

127. The semiconductor device of claim 124 further
comprising

a plurality of sense amplifiers adapted to precharge to a selected state or to latch a bit of information, a means to hold said sense amplifiers in an unmodified state after latching one of said bits of information, a means to precharge said sense amplifiers and a means for selecting whether said semiconductor device should precharge said sense amplifiers or should hold said sense amplifiers in an unmodified state.

128. The semiconductor device of claim 124 wherein said
is to respond to said information, where said information is
control information, further comprises a means to
transfer a data block during a data block transfer,
further including a means to
read data from said semiconductor device and
write data into said semiconductor device, and
initiate a data block transfer,
transfer a data block of a selected size,
transfer a data block at a selected time,
access a control register, including a means to read
from or write to said control register, or
select normal or page-mode access.

129. The semiconductor device of claim 124 further
rising a means to respond to said information in said request

packet if said information includes a device identification number unique to said semiconductor device.

130. The semiconductor device of claim 124 further comprising a means to respond to said information in said request packet if said information includes a special device identification number which calls for said semiconductor device to respond.

131. The semiconductor device of claim 124 further comprising a means to respond to said information in said request packet if said information includes an address unique to said semiconductor device.

132. The semiconductor device of claim 124 further comprising a means to interpret said control information and decode the time to wait before beginning said bus transaction over said bus.

133. The semiconductor device of claim 124 further comprising a means to interpret said control information and decode the size of a data block to transfer during one of said bus transactions.

134. The semiconductor device of claim 124, 125, 126, 127,
128, 129, 130, 131, 132 or 133 wherein said semiconductor device
is a memory device which connects substantially only to said bus
and sends and receives substantially all address, data and
control information over said bus.

5

135. A semiconductor device capable of use in a semi-
conductor bus architecture including a plurality of semiconductor
devices connected in parallel to a bus wherein said bus includes
a plurality of bus lines for carrying substantially all address,
data, control and device-select information needed by said
semiconductor device for communication with substantially every
other semiconductor device connected to said bus, and has
substantially fewer bus lines than the number of bits in a single
address, and carries device-select information for said
semiconductor device without the need for a separate device-
select line connected directly to said individual semiconductor
device, wherein said address, data, control and device-select
information is carried over said bus in the form of request
packets and bus transactions, said semiconductor device
comprising

connection means adapted to connect said semiconductor
device to said bus,
a means to encode address and control information in
said request packets and

25

a means to send said request packets over said bus.

136. The semiconductor device of claim 135 further

comprising a means to request a bus transaction wherein each of
5 said bus transactions is carried out in response to said address
and said control information in one of said request packets, and
wherein said means to encode information in said request packets
includes a means to mark a sequence of bytes on said bus as one
of said request packets, said control information including
10 information about the type of said bus transaction being
requested and the access time which needs to intervene before
beginning said bus transaction over said bus and said address and
said control information includes device-select information
instructing one or more said semiconductor devices to respond to
15 said address and said control information.

137. The semiconductor device of claim 135 wherein one or

more of said plurality of semiconductor devices has a unique
device identification number, said semiconductor device further
20 comprising a means to send control information to a specific one
of said plurality of semiconductor devices by including in said
request packet a selected said device identification number.

138. The semiconductor device of claim 135 wherein each of

25 said plurality of semiconductor devices is adapted to respond to
said plurality of semiconductor devices.

a special device identification number, said semiconductor device further comprising a means to send control information to each of said plurality of semiconductor devices by including in said request packet said special device identification number.

5

10 139. The semiconductor device of claim 135 wherein one or more of said plurality of semiconductor devices is a memory device having a plurality of addresses, said semiconductor device further comprising a means to send control information to a specific address or range of addresses in one of said plurality of semiconductor devices by including said specific address or range of addresses in said request packet.

10

15 140. The semiconductor device of claim 135 wherein at least one of said request packets is a request packet requesting a bus transaction which is followed by a corresponding one of said bus transactions, said semiconductor device further comprising a means to encode said control information to specify directly or indirectly the time between the end of said request packet requesting a bus transaction and said corresponding bus transaction over said bus.

20

25 141. The semiconductor device of claim 140 wherein one type of said bus transactions is a transfer of a data block, said semiconductor device further comprising a means to encode said

control information to specify the size of said data block to transfer.

142. The semiconductor device of claim 140 further comprising a means to keep track of current and pending bus transactions, whereby collisions on said bus are avoided because said semiconductor device avoids initiating bus transactions which would conflict with current or pending bus transactions.

143. The semiconductor device of claim 135 wherein said semiconductor device is a first master device and one of said plurality of semiconductor devices is a second master device, further comprising

a collision detecting means whereby said first master device when sending a first one of said request packets can detect said second master device sending a colliding one of said request packets, where said colliding request packet may be sent simultaneous with the initial sending of or overlapping the sending of said first request packet, and

an arbitration means whereby said first and said second master devices select a priority order in which each of said master devices will be allowed to access said bus sequentially.

144. The semiconductor device of claim 143 wherein said semiconductor device is a master device and at least one of said plurality of semiconductor devices is a master device, each of said master devices has a master ID number and each of said 5 request packets includes a master ID position which is a predetermined number of bits in a predetermined position in said request packet, and wherein said collision detection means comprises

10 a means for said semiconductor device to send its master ID number in said request packet and a means to detect a collision and invoke said arbitration means if said semiconductor device detects any other master ID number in said master ID position.

15 145. The semiconductor device of claim 144 wherein said system bus architecture includes a means for carrying information on said bus during bus cycles, said semiconductor device further comprising

20 a means for driving a selected bus line or lines during at least one selected bus cycle while sending each said request packet,

a means for monitoring said selected bus line or lines to see if another said master device is sending one of said colliding request packets and

a means for informing all said master devices that a collision has occurred and for invoking said arbitration means.

5 146. The semiconductor device of claim 145 further comprising

a means, when sending a request packet, for driving a selected bus line or lines with a certain current during at least one selected bus cycle,

10 a means for monitoring said selected bus line or lines for a greater than normal current to see if another said master device is driving that line or lines,

15 a means for detecting said greater than normal current, and

a means for informing all said master devices that a collision has occurred and for invoking said arbitration means.

20 147. The semiconductor device of claim 143 wherein said arbitration means comprises

a means for initiating an arbitration cycle,

a means for allocating a single bus line to each said master device during at least one selected bus cycle relative to the start of said arbitration cycle,

5 a means for allocating each said master device to a single bus line during one of said selected bus cycles if there are more master devices than available bus lines,
a means for each of said master devices which sent one of said colliding request packets to drive said bus line allocated to said master device during said selected bus cycle, and

10 a means in at least one of said master devices for storing information about which master devices sent one of said colliding request packets,

15 whereby said master devices can monitor selected bus lines during said arbitration cycle and identify each said master device which sent one of said colliding request packets.

148. The semiconductor device of claim 143 wherein said arbitration means comprises

20 a means for identifying each of said master devices which sent one of said colliding request packets,

a means for assigning a priority to each said master device which sent one of said colliding request packets, and

25 a means for allowing each said master device which sent one of said colliding request packets to access the bus sequentially according to that priority.

149. The semiconductor device of claim 143 wherein said priority is based on the physical location of each of said master devices.

5 150. The semiconductor device of claim 143 wherein said priority is based on said master ID number of said master devices.

10

ABSTRACT

The present invention includes a memory subsystem comprising at least two semiconductor devices, including at least one memory device, connected to a bus, where the bus includes a plurality of bus lines for carrying substantially all address, data and control information needed by said memory devices, where the control information includes device-select information and the bus has substantially fewer bus lines than the number of bits in a single address, and the bus carries device-select information without the need for separate device-select lines connected directly to individual devices.

The present invention also includes a protocol for master and slave devices to communicate on the bus and for registers in each device to differentiate each device and allow bus requests to be directed to a single or to all devices. The present invention includes modifications to prior-art devices to allow them to implement the new features of this invention. In a preferred implementation, 8 bus data lines and an AddressValid bus line carry address, data and control information for memory addresses up to 40 bits wide.

REQUEST TO APPROVE DRAWING CHANGES

Dear Sir:

Applicants seek to amend Figure 10 to more fully reflect the discussion in the specification, specifically, page 55, line 12-16 and page 58, lines 13-23. Attached is a photocopy of Figure 10 with the proposed changes indicated in red. No new matter has been added.

Applicants respectfully request approval of the proposed changes. A new Figure 10 which incorporates the changes is also attached to hereto.

Respectfully submitted,

Neil A. Steinberg

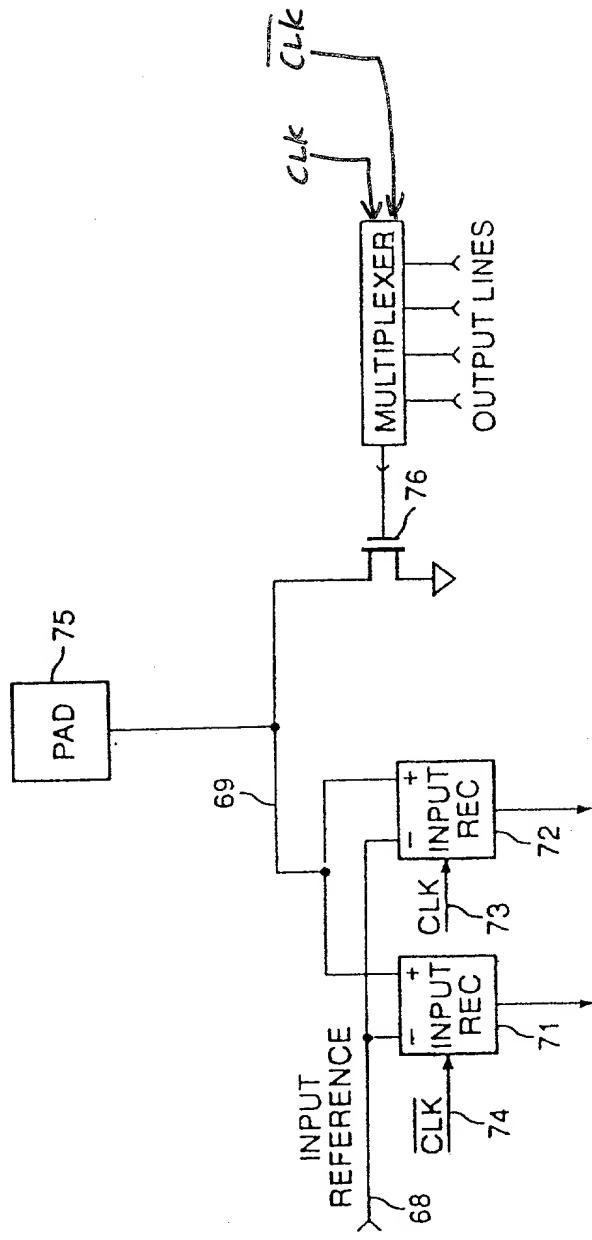

FIG. 10

Our Ref.: RamBus D-1

DECLARATION AND POWER OF ATTORNEY FOR PATENT APPLICATION

As a below named inventor, I hereby declare that:

My residence, post office and citizenship are as stated below, next to my name.

I believe I am the original, first and sole inventor (if only one name is listed below) or an original, first and joint inventor (if plural names are listed below) of the subject matter which is claimed and for which a patent is sought on the invention entitled INTEGRATED CIRCUIT I/O USING A HIGH PERFORMANCE BUS INTERFACE the specification of which

XX is attached hereto.

_____ was filed on _____ as
Application Serial No. _____
and was amended on _____
(if applicable)

I hereby state that I have reviewed and understand the contents of the above-identified specification, including the claims, as amended by any amendment referred to above. I do not know and do not believe that the same was ever known or used in the United States of America before my invention thereof, or patented or described in any printed publication in any country before my invention thereof or more than one year prior to this application, that the same was not in public use or on sale in the United States of America more than one year prior to this application, and that the invention has not been patented or made subject of an inventor's certificate issued before the date of this application in any country foreign to the United States of America on an application filed by me or my legal representatives or assigns more than twelve months prior to this application.

I acknowledge the duty to disclose information which is material to the examination of this application in accordance with Title 37, Code of Federal Regulations, Section 1.56(a).

I hereby claim the benefit under Title 35, United States Code, Section 120 of any United States application(s) listed below and, insofar as the subject matter of each of the claims of this application is not disclosed in the prior United States application in the manner provided by the first paragraph of Title 35, United States Code, Section 112, I acknowledge the duty to disclose material information, as defined in Title 37, Code of

PRINT OF DRAWINGS
AS ORIGINALLY FILED

Federal Regulations, Section 1.56(a) which occurred between the filing date of the prior application and the national or PCT international filing date of this application:

I hereby appoint Roger S. Borovoy, Reg. No. 20,193, and David J. Larwood, Reg. No. 33,191, 600 Hansen Way, Suite 100, Palo Alto, California 94306, telephone (415) 856-9411, my attorneys with full power of substitution and revocation, to prosecute this application and to transact all business in the Patent and Trademark Office connected herewith. Please address all correspondence to Mr. Larwood.

I hereby declare that all statements made herein of my own knowledge are true and that all statements made on information and belief are believed to be true; and further that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under Section 1001 of Title 18 of the United States Code and that such willful false statements may jeopardize the validity of the application or any patent issued thereon.

POWER OF ATTORNEY BY ASSIGNEE,
REVOCATION OF ALL PRIOR POWERS OF ATTORNEY
AND
CERTIFICATE UNDER 37 CFR 3.73(b)

Sir:

The undersigned, being empowered to sign this Power of Attorney, Revocation of All Previous Powers of Attorney and Certificate under 37 CFR 3.73(b) on behalf of Rambus, Inc., the assignee of the entire right, title and interest in the above-referenced application, hereby revokes all prior powers of attorney and hereby appoints Neil A. Steinberg, Reg. No. 34,735, with full power of substitution and revocation to prosecute this application and to transact all business before the United States Patent and Trademark Office in the above-referenced application.

Rambus, Inc., formerly a California corporation with a place of business at 4920A El Camino Real, Los Altos, California 94022, certifies that it is the assignee of the entire right, title and interest in the above-referenced patent application by virtue of an assignment from the inventors, Michael Farmwald and Mark Horowitz. The assignment of the parent patent application (Application Serial

No. 07/510,898) and all continuing and divisional application thereof to Rambus Inc. was filed on April 18, 1990 and recorded in the U.S. Patent and Trademark Office at Reel 5385, Frame 875.

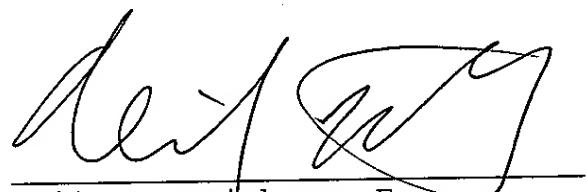

The undersigned has reviewed all the documents in the chain of title of the above-referenced application and, to the best of the undersigned's knowledge and belief, title is in Rambus, Inc., the assignee identified above.

Please direct all correspondence in the above-referenced patent application to:

Neil A. Steinberg, Esq.
Rambus Inc.
2465 Latham Street
Mountain View, California 94040
Telephone: 650-944-7772
Facsimile: 650-944-8080

I hereby declare that all statements made herein of my own knowledge are true and that all statements made on information and believed to be true; and further that these statements were made with the knowledge that willful false statements and the like so make are punishable by fine or imprisonment, or both, under Section 1001 of Title 18 of the United States Code, and that such willful false statements may jeopardize the validity of the application, any patent issuing thereon.
